Richard Clark wrote:
> You still show signs of confusion. Phase shift in what?

I have explained it twice already. Given the following
4-terminal network impedance discontinuity at '+':

---43.4 deg 600 ohm line---+---10 deg 100 ohm line---open
Vfor1-->|-->Vfor2

What is the phase shift in the forward voltage at the
impedance discontinuity? The forward voltage on each
side of the impedance discontinuity , '+', is not
equal in magnitude or phase.

We know the stub causes a 90 degree phase shift end to
end. Since there is 43.4 deg phase shift in the 600 ohm
line and 10 deg phase shift in the 10 ohm line, guess
what the phase shift in the forward voltage has to be
at the impedance discontinuity?

Also previously explained, if you prefer - in s-parameter
terms: What is the phase shift between a1 and b2 in the
s-parameter equation:

b2 = s21*a1 + s22*a2

If you were locked in a black box, you would be ignorant
of night and day. Does that mean that night and day would
not be happening? Hint: No, it would just mean you are
ignorant. Your ignorance changes absolutely nothing
outside of the box in which you are locked.

Why does my ignorance of what's in the black box change
the reality of what's in the black box? Hint: it doesn't.

The fact that I am ignorant of the four terminal network
in the box doesn't change the fact that it is a four
terminal network. The fact that you won't allow me to
open the box and measure the phase shift at the impedance
discontinuity doesn't change the fact that it is 36.6
degrees.

OK, So you are ignorant of what is inside the box. Rather a long
ramble to such a simple conclusion.

Are you still ignorant of which of two phases? Your rambling
confusion has yet to come to terms even to the point of not being able
to name both of them in one posting!

Like trying to wake a sleep-walker, I hesitate to offer a dangerous
suggestion with you in your condition: Could they be "phase" shift
and "phase" length? In your somnambulant state of foggy recall
>>It just occurred to me that you and I may be talking
>>about two different phases.
can you tell the group what the two different phases are? This could
be an important moment in recovery (it may take only 11 steps more).

Take your time, we appreciate that your sudden catharsis can jog your
mind into curious responses...even though they would be

indifferentiable from the several hundred that preceded. ;-)

Richard Clark wrote:
> Are you still ignorant of which of two phases?

I have spelled out the desired phases three times now.
This will be the forth time.

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2

The phase shift we are looking for is between Vfor1
and Vfor2. I might as well perform the calculations
for you since you seen to be incapable of doing so.

If we assume a reference of 100 volts at zero degrees
incident upon the open end of the stub, then back at
the impedance discontinuity:

Vfor2 = 100 volts at -10 deg.
Vfor1 = 143.33 volts at -46.6 deg

The phase shift between Vfor1 and Vfor2 is 36.6 degrees
just as it has to be for a 90 degree phase shift to
occur end to end in the above 1/4WL stub.

Vref2 = 100 volts at 10 deg
Vref1 = 143.33 volts at 46.6 deg

Cecil,

This appears to be an unusual definition. How does the "point where two pieces of feedline are connected" become a four-terminal network? One typically thinks of a four-terminal network as having inputs and outputs, with something between. What is that "something between" in the case of two connected feedlines? In your models this "something" seems to have no dimensions and no characteristics other than a phase shift.

Are you suggesting that every simple connection is now a four-terminal network? Do all of the textbooks need to be re-written?

73,
Gene
W4SZ

You have many explanations that don't actually answer questions. Your
confusion, as evidenced in the sudden realization:
>It just occurred to me that you and I may be talking
>about two different phases.
doesn't really tell us what phase shift. Perhaps if you could state
what the two are, and which you are using, the rest of us would be
satisified you are no longer confused.

Or maybe everyone is actually on the same page with only one phase
being mentioned, and some alternate phase expression (yet to be
revealed by you) is tormenting your imagination and corrupting your
answers with their math errors.

According to the equation you provide above, for any point location 'x', the phase of the current varies continuously with t. Presumably that is what it means to just oscillate in place.

Not unusual at all, Gene. The two input terminals to the
black box are on one side. The two output terminals from
the black box are on the other side. The impedance
discontinuity is inside the box. The black box is extremely
small.

Give me the four s-parameters, s11, s12, s21, and s22
and I can tell you virtually everything about what is
inside the black box without even applying a signal.

Fourth. (You suffer from spelling as well as logic, theory, math...
errors. Yes, you freely admit to all of this, but stop wringing your
hands, we all know it merely exhibits the eccentric's classic signs of
that 260 IQ.)

However, the assembled group (loitering in the wings, amused at this
comic duo) will agree you've arrived at some form of conclusion
quicker than in 20 dips into memory's poisoned well. Your netzheimers
must be in 16/20ths (as in (20 - 4)/20) remission. Would that be
computed to square law to specify your recall at -1.94dB? Perhaps
not. Random scraps of error free math does not impart validity.

BZZZT! Wrong answer.

Nobody ever said anything about the "other side" of the black box.
Everything has been referenced to "the point where two pieces of
feedline are connected."

Nobody is trying to suggest that what is inside one black box is
identical to what is inside another black box. The only thing known is
that the *two* accessible terminals to each of the black boxes show the
same specific impedance at the given frequency. Nothing else. Yet by
your models and math the black boxes don't behave the same in your test
circuit.

You still have not addressed the original question posed by Keith.

Well, for an admitted MENSA member (or lapsed member, which gives the
impression of a limp pendant) also having troubles in catching math
errors, or confused dualities; then it stands you must also be warned
a spell checker doesn't validate syntax, nor the validity of
expression.

As I know you stumble over English, I will put it in Texican:
"Random math does not validate irrational theory;
Xeroxed words littered on the page does not sell snake oil."
(OK, so it is more like cowboy couplet haiku.)

>I knew it was
>only a matter of time until you stooped to complaining

Netzheimers remission is clearing the fog, is it?

>close to as low as a person can
>stoop. Your ulterior motive here is clear to all.

"All" seem to be very few (except for those chuckling in the wings).

*** So, moving back to the technical side of the balance sheet. ***

No problems with my math assuming the square law computation of your
recall at -1.94dB? I thought you might want to boost it to 19/20ths
with having to only say it once and suffer a recall of -0.45dB.

Was that a new low? This exterior motive was especially formulated
for your the sake of your depressed recall response curve. ;-)

So that you can preserve your dignity - I will leave you the last
word. And remember, always leave them laughing (think of it as
another theory you are introducing).

> internet--and especially in remote situations is only real and logical
> ...

Nope. It's imaginary and illusionary.

Wireless ISPs are here now and serving areas not served by cable or DSL and doing so much more efficiently than BPL will ever hope to. With our recent ice storm, my WISP kept right on working as long as I had power. If BPL had been employed, it's likely that it would be weeks before the power companies would re-establish Internet service. Getting AC power to people is their first priority and ISP would be far down their list. Meanwhile Internet service is the priority for my WISP.

When the rural power grid is understood, it becomes obvious that BPL is a political solution in search of a problem.

Harold!

I resemble that earmark!

Add 100 indeed, I thought it was 200.

As for your last sentence. The "he" is rather unspecific as two
correspondents made a promise (perhaps not so well timed as to fit
your observation here). However, I too will sit on the edge of my
seat in wonderment to that outcome.

Of course, that's what it means. It doesn't move right or left.
I(x,t) = Imax sin(kx) cos(-wt) would be just as accurate a
description. One cannot even tell which way the standing-wave
phasor is rotating. This equates to putting the source
on either end of a lossless stub without anything changing.
Standing-wave current phase is unchanging up and down a lossless
stub. Standing-wave current phase changes hardly at all up and
down a stub with losses or a wire 1/2WL dipole. That current
cannot be used to obtain a valid delay through a wire or a coil.

Roy, you are always saying I should be using voltages for
my calculations and that's exactly what I did.

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2

With 100 volts at zero degrees incident upon the open
end of the stub, I get:

Vfor1 = 143.33 volts at -46.6 deg
Vfor2 = 110 volts at -10 deg

for a phase shift through the impedance discontinuity
of 36.6 degrees. What do you get?

Don't anybody hold his breath waiting for an answer.
The Emperor has no clothes.

From: "-.-. --.-" <A@A.COM>
Message-ID: <fk6rqa$5tv$1@nnrp-beta.newsland.it>
Source record: 31203

Hi there,

i'm thinking about build from scratch on the roof of my house a lightweight random vertical antenna (with small pvc tubes or fishing rod) feeded by an automatic ATU. The same antenna with some kind of leverage will be erectable from 0° to 90° (plain to my *plain* roof) to avoid & prevent lightning but this is a mechanical history... so:

Many posts about the Rybakov antenna reports the use of a 4:1 UN-UN. I'm not sure about the real needs of this kind of un-un... you readers what have to suggest about height and un-un if you have to build a random vertical to cover 80-6 meters with a decent efficiency ??

TIA,

t changes hardly at all referenced to the source current
phase which is what we are talking about. Please don't
try to feign ignorance of that fact. What I don't get is
why people like you have to distort the technical facts.
What do you possibly have to gain through distortion and
diversion?

The phase is referenced to the source phase, as it is in EZNEC,
but you already knew that and just want to perform your usual
diversions away from the technical facts.

I have said at least a dozen times that the current phase
I am talking about is the same as EZNEC reports. If you don't
like what EZNEC reports, take it up with Roy.

For those who don't understand Jim's diversion above, EZNEC
sets t=zero as a reference and then reports the phase. Jim
knows that and is just trying to hoodwink the uninitiatated.
His motives for such remain a mystery.

OK Robert. (Howard was my uncle. He has the orange top). No, I just knew that you were into metrology from your postings, and I had the PMEL at Hickam 1960-63.

Now that you've explained that, I'll inquire someday (but not today) as to what the SUBLANT folks were doing in the Pacific.

forget the un-un, just feed it direct with coax and put as many radials
under it as you can. most of the efficiency questions are then due to the
tuner.

Actually, I'm trying to figure out what technical meaning there is to be obtained from your repeated observation "Standing-wave current phase changes hardly at all up and down a stub with losses or a wire 1/2WL dipole." The phase of the standing wave varies with position from one perspective, and with time from another, and with amplitude from yet another. If you hold t fixed, then amplitude and position remain variable. This is a revelation?

Most of us would understand efficiency as you have used it to mean the
ratio of radiated power to antenna system input power.

An unloaded monopole system that is long enough to be reasonably efficient
at 80m (say > 13m) will have a radiation pattern that is most unattractive
at 6m where you would depend on low angle performance for most contacts.

Owen

The current reported by EZNEC isn't referenced to source phase. The phases of all currents and voltages -- wire, source, and load -- are all referenced to the same arbitrary point. Source phase can be assigned by the user to any value relative to this point.

As far as I can tell, Cecil has never been quite able to understand just what EZNEC reports. EZNEC doesn't need several different definitions of current to suit the theory du jour or to do its job, so it doesn't report "standing wave current" or other fruits of The Gifted One's overly fertile imagination. It simply reports current. Anyone not acquainted with this concept can refer to any basic text on electricity or physics. What EZNEC reports is exactly what you'll find there.

What was that question? I suspect the question was irrelevant
because Keith didn't understand what phase shift I was talking
about. I also suspect that Keith is beginning to understand
what I am talking about. His silence seems a little strange.
What are you going to do when your realize you are on the
wrong side of the technical argument? Sandbag - like some
others have done and try to obscure the technical facts?

How about an answer from you? What is the phase shift through
the impedance discontinuity between Vfor1 and Vfor2 below?

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2

I doubt that you even know how to solve the problem. Your lack
of an answer will speak volumes.

Take a look at the current reported by EZNEC and you will
understand. Until you do that, I'm afraid you will just
continue to show your ignorance.

Hint: Given a reference zero phase for the source signal,
EZNEC reports all current phases with respect to that
source phase. So either choose to understand or remain
ignorant - I just don't care which.

The phase assigned by the user to the source obviously becomes
the default reference phase. What on earth do you have to gain
by obscuring that technical fact?

If the user doesn't do anything, the source phase defaults to zero
and all current measurements are referenced to that zero source
phase. Are you so determined to discredit me that you are willing
to sacrifice your integrity in the process?

Do you deny that there is virtually no phase shift in the current
up and down a 1/2WL dipole referenced to the source current. If you
are up to that denial, please argue with Kraus's graphic. Take a look
at the phase angles at:

http://www.w5dxp.com/krausdip.jpg

Unfortunately, Kraus agrees with EZNEC and that current is
exactly what you used to make your meaningless measurements
of current phase through a loading coil. So please look at
Kraus's graph and tell us again how that current with unchanging
phase can be used to measure phase shift through a loading coil.

My point exactly! If the antenna being modeled is a standing-wave
antenna, EZNEC reports standing-wave current.

If the antenna being modeled is a traveling-wave antenna, EZNEC
reports traveling-wave current. Roy apparently doesn't want anyone
to know this fact.

So Roy, why would the phase shift through a coil be different
when it is used in a 1/2WL dipole vs using it in a rhombic
at the same frequency??? Magic???

Roy has threatened to take EZNEC away from me for using it to
demonstrate traveling-wave current through a loading coil. Here
is what EZNEC says about the delay through that loading coil.

http://www.w5dxp.com/coil512.ez

Click on "Load Dat" and observe what Roy is so afraid that
someone besides me is going to discover.

Hmm, still confused about two different phases? In all of four lines
you whip-saw from knowing it all to knowing nothing at all for what
appears to be the same phase.

At the fear of being presumptions, why don't you move the source 77
degrees along the radiator? Or insert a line 77 degrees long (which
phase?). Or insert a lumped reactance that offers 77 degrees phase
(which phase?).

This is getting fun. Who woulda thunk? :-)

I've just solved the phase duality problem!!!!!!!!! [observe above]

Set your system clock to CST when you design the
circuit/antenna/whatever and then reset your system clock to GMT
before you press the Currents button.

That should give you 90 degrees shift. Sorry, but this method only
works in cardinal points of 15 degrees. Perhaps there is some
neighboring county that uses Mars Twilight Savings Time for finer
granularity.

It's probably a matter of perspective, because from here it seems that you are the one reporting the nonsensical results. I use Mathcad and Sigma Plot for plotting functions like I(x,t) = Imax sin(kx) cos(wt). Maybe you could give one of those a try.

When you do that, how does this show up in the coordinates? For example, you
have the sinusoid with I(x,t) as the Y axis and x as the distance axis.
Then I suppose t is shown on the z axis so in 3-D view you have a sine wave
and a cosine wave 'surface' intersecting at right angles. I would like to
see that plotted in a 3-D view in a CAD program. Unfortunately I have no
access to such software.

Sorry, EZNEC doesn't use that equation. EZNEC needs a
reference phase. Roy seems to know how to make that
reference a different phase angle than the specified
source phase angle but I don't know how to do that.

Here's the plot for that equation above:

http://www.chemmybear.com/standing.html

Obviously, EZNEC cannot report those results in tabular
form.

Gene Fuller wrote:
> Do you also open the (black) box to see how Schroedinger's cat is doing?

I do whatever I need to do to solve the problem, Gene.
If I have to open the box to see if the cat is dead
or alive, that's what I will do. I do not believe in
erecting silly artificial barriers in the quest for
knowledge - and we are not talking about a quantum
physics paradox.

So let me repeat: The phase shifts at the -j567 points
in the two following 1/4WL stubs are not the same.

--43.4 deg 600 ohm line--+--46.6 deg 600 ohm line--open

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open

The phase shift at '+' in the 1st example is zero.

The phase shift at '+' in the 2nd example is 36.6 deg.

I'm well aware of what the math models show, Jim.

Let's say we have current probes installed at
'x' and 'y' in a 1/4WL wire. 'x' and 'y' are
30 degrees apart.

We apply a standing wave with the equation
I(xt) = Imax*cos(kx)*cos(wt)

source------------x---------------y-------------open

What will be the relative phase difference between
the current measured at 'x' and the current measured
at 'y'?

Now apply a traveling wave with the equation
I(x,t) = Imax*cos(kx+wt)

source------------x---------------y-------------load to ground

What will be the relative phase difference between
the current measured at 'x' and the current measured
at 'y'?

This experiment has been in disfavor ever since the advent of the PETA
organization. They did not support the uncertainty of the cat being living
or dead or in some models, of being both living *and* dead, on average. So
they always attempted to observe the cat, not knowing that they themselves
were the ones who defined the dire fate of the cat by simply observing it. I
myself would never attempt to observe the cat in Schrodinger's box since it
is not definitive of the state of the cat prior to observation. I do not
believe the same is true of the -j567 ohm impedance in Keith's box ;-)

Hi Dan,

Mathcad allows for as many coexisting simultaneous axis as you care.

As for 3D, this is called a contour plot (which can be done either flat, or with relief). Excel will do this too (but with no particular panache).

Seeing you are funds challenged, search the web for OpenDX (an IBM project deeded to the public domain, and otherwise called Data eXplorer). It can do the same thing. There is also a package called XD3D, that is also from the OpenSource community.

The IBM package is the one most used by the research community; or at least the ones I've been attending for 7 years.

3567. Standing-Wave Current vs Traveling-Wave Current

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-18 15:33:23 UTC
From: Cecil Moore <nospam@w5dxp.com>
Message-ID: <7LR9j.133$EI5.122@newssvr22.news.prodigy.net>
Source record: 31233

There seems to be mass confusion even among the gurus on
this newsgroup as to the difference between standing-wave
current, as exists on a 1/2WL dipole, vs traveling-wave
current, as exists on a terminated antenna like a rhombic.

I have prepared two EZNEC files that should run on the
free demo version of EZNEC as well as on the commercial
edition. These two files clearly show the difference in
the two types of currents.

The standing-wave example is designed to illustrate
standing-wave current. All of the forward energy is
reflected at the open end of the wire. The total
current displayed by EZNEC is the sum of the forward
and reflected currents which are close to equal.

The traveling-wave example is designed to illustrate
traveling-wave current. Most of the forward energy
is dissipated in the load resistor rather than being
reflected. The total current displayed by EZNEC is
the sum of the forward and reflected currents with
the reflected current minimized to a negligible value.

Each EZNEC file consists of a 1/4WL wire run horizontal
one foot above ground at 4 MHz. In the standing-wave file,
the wire is open and unterminated. In the traveling-wave
file, the wire is terminated to ground by its characteristic
impedance. To view EZNEC's tabulated current at each of the
18 segments along the 1/4WL, simply click on "Load Dat".

The standing-wave file is:

http://www.w5dxp.com/StndWave.EZ

The traveling-wave file is:

http://www.w5dxp.com/TravWave.EZ

In the following results (directly from EZNEC) please
note the almost constant phase reported for the
standing-wave current vs the continuously changing
phase reported for the traveling-wave current.

Here are the values of current at each segment for the
standing-wave example as reported by EZNEC:

EZNEC+ ver. 4.0

```
standing wave 12/18/2007 9:11:33 AM
--------------- LOAD DATA ---------------
Frequency = 4 MHz

Load 1 Current = 0.9974 A. at -0.01 deg.
Load 2 Current = 0.9874 A. at -0.02 deg.
Load 3 Current = 0.9703 A. at -0.03 deg.
Load 4 Current = 0.9461 A. at -0.04 deg.
Load 5 Current = 0.915 A. at -0.05 deg.
Load 6 Current = 0.8773 A. at -0.06 deg.
Load 7 Current = 0.8332 A. at -0.07 deg.
Load 8 Current = 0.783 A. at -0.08 deg.
Load 9 Current = 0.7271 A. at -0.08 deg.
Load 10 Current = 0.6659 A. at -0.09 deg.
Load 11 Current = 0.5999 A. at -0.09 deg.
Load 12 Current = 0.5295 A. at -0.10 deg.
Load 13 Current = 0.4553 A. at -0.10 deg.
Load 14 Current = 0.3777 A. at -0.10 deg.
Load 15 Current = 0.2974 A. at -0.10 deg.
Load 16 Current = 0.2148 A. at -0.11 deg.
Load 17 Current = 0.1307 A. at -0.11 deg.
Load 18 Current = 0.0447 A. at -0.11 deg.

Here are the values of current at each segment for the
traveling-wave example as reported by EZNEC:

EZNEC+ ver. 4.0

traveling wave 12/18/2007 9:18:19 AM
--------------- LOAD DATA ---------------
Frequency = 4 MHz

Load 1 Current = 0.9992 A. at -3.12 deg.
Load 2 Current = 0.9983 A. at -8.11 deg.
Load 3 Current = 0.9977 A. at -13.08 deg.
Load 4 Current = 0.9972 A. at -18.05 deg.
Load 5 Current = 0.9970 A. at -23.02 deg.
Load 6 Current = 0.9970 A. at -27.99 deg.
Load 7 Current = 0.9973 A. at -32.96 deg.
Load 8 Current = 0.9978 A. at -37.92 deg.
Load 9 Current = 0.9985 A. at -42.87 deg.
Load 10 Current = 0.9993 A. at -47.82 deg.
Load 11 Current = 1.0000 A. at -52.75 deg.
Load 12 Current = 1.0010 A. at -57.67 deg.
Load 13 Current = 1.0030 A. at -62.58 deg.
Load 14 Current = 1.0040 A. at -67.48 deg.
Load 15 Current = 1.0050 A. at -72.36 deg.
Load 16 Current = 1.0060 A. at -77.23 deg.
Load 17 Current = 1.0070 A. at -82.09 deg.
Load 18 Current = 1.0080 A. at -86.97 deg.

Hi Cecil,

I tried the files and they work well. Congratulations on a clever use of zero resistance loads. I have not seen that technique used before but it certainly allows for a good EZNEC demonstration.

EZNEC is a great program.

It's a way to "measure" the current without disturbing the current. Do you see how the EZNEC current has a reference phase and thus is a "snapshot" in time? Do you see how traveling-wave current travels and standing-wave current just appears to stand there? Since EM waves cannot just stand there and must necessarily move at the speed of light, a standing-wave is just an artifact of superposition (a magical illusion for some). It has no stand-alone existence aside from its forward and reverse component EM waves that indeed do travel at the speed of light (adjusted for velocity factor).

> EZNEC is a great program.

Yes indeed, like the Smith Chart, it is a great antenna tool. I've been a satisfied customer for 20 years, since I first purchased ELNEC. ELNEC and EZNEC have been great tutors for me. If someone doesn't want to buy it, the free demo version of EZNEC available from http://www.eznec.com is quite a free lunch and although limited to 20 segments, is very useful on wire dipoles and monopoles and learning how they work.

I already know what a static 3D plot would like like. But to put it in
motion, including the illustration of the forward and reflected length
over distance x; showing the surface of periodic waves for each value
of x; that would be a nice visual.

In the real world, the person who manufactured our
black box in the first place has already collapsed the
probability function a long time ago. Now if that
person dies without telling anyone what's in the black
box, does the black box's contents revert to any
possibility? :-)

The difference is that Schrodinger's cat can die at any
time but the inanimate contents of our black box cannot
change with time. If we don't know what's in the black
box, we are simply ignorant. What we know or don't know
does not effect or affect the reality of what's already
in the black box.

I'm sorry, Roy, I just changed the source phase in a single
source system and changed nothing else. The reported phase of
the antenna currents changed in step with the source phase.
Since all you did was provide a GUI interface to NEC, might
it be possible that you don't understand how NEC works?

I looked at travstnd the first time you posted it, and I even commented to you about it. I assume that coil512.ez is what you used to create the plot on the left that says "No Phase information in the Magnitude" and has the words "Straight Line" by the straight line. It's all very scientific. :-)

Let me ask you this: how would you go about calculating the phase shown on your Standing Wave Current graph, and what meaning if any does it hold for you?

Cecil,

I think you are misunderstanding Roy's response. If the currents were referenced to the source phase, they would not change when the source phase was changed. That observable fact that the antenna current phases do change when the source phase is changed supports Roy's explanation completely.

:-)
Confusion appears to be selective here, and not to be found generally
in the remainder of the group.

For instance, in the quote above, we are introduced to two antennas
THAT ARE NEVER AGAIN EMPLOYED, AS EXPLICITLY INFERRED, AS THE BASIS OF
COMPARISON!

In short, the author immediately dismissing these practical antennas,
never again approaches the problem as described above. The solution
to this confusion appears to be of no true concern. So, what's the
problem? No question follows in the remainder of the post, only
statements. No statements illustrate the difference between any
antennas that are the source of the presumed confusion. The original
model wires draped 1/200th wavelength above ground are certainly not
to be confused with conventional rhombic, nor dipoles.

Diligent readers would back away from this dead horse.

Modeling a rhombic is not outside the art of the practitioner, only
one practitioner for whom the data does not support the premise for
these antennas (quickly discarded as I have pointed out).

Four 4 wavelength wires built into a symmetric diamond, one source at
22MHz, one load, and the whole model is described. As a variation,
put it in free space, test; repeat with it 65 feet above ground, test.
As another variation, load with a matched R, test; load with an
open/short, test.

What monumental results follow from all results?

65 feet above ground we observe:
w/Rl = 816 Ohms:
I magnitude declines end-to-end due to radiation;
I magnitude varies insignificantly seg-to-seg (<<1%);
I phase varies ~160-~100 degrees per 10 segments;
I phase inverts every 10 segments.
w/Rl = 1e9 Ohms:
I magnitude declines end-to-end due to radiation;

I magnitude varies seg-to-seg (~10%-~40%);
I phase varies ~160-~100 degrees per 10 segments;
I phase inverts every 10 segments.

In free space we observe:
w/Rl = 816 Ohms:
I magnitude declines end-to-end due to radiation;
I magnitude varies insignificantly seg-to-seg (<<1%);
I phase varies ~160 degrees per 10 segments;
I phase inverts every 10 segments.
w/Rl = 1e9 Ohms:
I magnitude declines end-to-end due to radiation;
I magnitude varies seg-to-seg (~5%-~25%);
I phase varies ~160 degrees per 10 segments;
I phase inverts every 10 segments.

All variations support the notion of traveling and standing wave antennas (unless, of course, some novel re-definition of terms is injected into the debate). The presumption of traveling waves is well defined in the current data when placing a "matched load" on the antenna-as-transmission line is performed. The presumption of standing waves is well defined in the current data when the "matched load" is opened on the antenna-as-transmission line.

What does not conform to well tailored expectations? The phase swings under all conditions are well defined, extensive, and repeat with regularity. Further, we can also observe how ground's proximity, even with a substantial height against wavelength begins to intrude into current dynamics.

We can then proceed into where confusion might reside (it not being found in these antennas): GROUND. Yes, the death embrace of the original models with GROUND profoundly skews the data. I would note that there is the usual crafting of the original post to insure plausible deniability. In short, the reader is left to be astonished by the data (corrupt as it is, given the tantalizing premise of Rhombics and Dipoles being so confusing to the crowd of readers) and to then be lead further away from that initial dismissal of those antennas, only to be drawn back to them through Byzantine extrapolations and copious mathematical "proofs."

As always, fun. I doubt anything new in the technical vein will follow, so I look forward to the parade that is sure to fill this thread.

Hi Dan,

I've already offered that solution. I have been using OpenDX to do
this for some time now. Have you looked at my suggestions?

But the rules for black boxes do not allow measurements
on the inside. This is how they help clarify the thinking.

> This is an example of how models can get you into trouble.
> Not allowing us to look inside the black box doesn't change

Nor has that been claimed.

> It just means that the phase shifts are unknown and need
> to be measured.

As you say, the phase shifts are unknown so from
my list of possible answers, I would have recommended
selecting

4) undecidable

but this leads to it also being

6) irrelevant

since the problem can be solved without the information.

>original models with GROUND profoundly skews the data.

Hi All,

Well, I find there is more technical content to dissect in at least
one dead horse.

Let's look at the "traveling wave" model and see what it has to offer
in the cold harsh light of reality.

Right off the bat with its performance: -23.74dB
What could possibly account for all this loss? The "load?"?

Instead of tossing the load, let's toss ground and put this corpse in
free space. It's performance: -0.30dB

I don't know how any math error like this could be used to validate a
model, but the efficiency as an antenna that hugs ground so vigorously
hardly measures up to either a dipole or a rhombic. On the plus side,
confusion certainly offers many vendors an income, and suckers are
born every minute who would love a low noise antenna.

However, what happened to the currents when we discarded ground? Well,
the pristine constant current of the former model plunges right down
the toilet of expectations (while performance shot through the ceiling
at the same time - one has to wonder what was confusing about this?).
Phase change? That cute 90 degrees formerly nudged and cosseted onto
center stage has now been nailed to the floor with no more total
variation than 2.15 degrees. Hard to imagine how a transmission line
could so thoroughly rape its inventor.

Turning to the "standing wave" model, would it be instructive how a
ground free performance might similarly fare?

Right off the bat with its performance: -1.69dB
it would seem a stretch to find any more efficiency (and shows how
that traveling wave model really sucks). However, without ground for
completeness' sake: -0.28dB

However, what happened to the currents when we discarded ground? Well,
roughly the same 2 degree shift we found when the "traveling wave"
model split the sheets with ground, but beyond that, an almost
identical current taper and phase lock-down found with the "traveling

wave" model free of ground (or in comparison to itself close to ground).

So, is there any substantial difference between the two models once ground's death grip is released? I will leave that question for tea-leaf analysis, because engineers would have buried this dead horse long ago.

***** Irony meter pegged *****

I would like to point out that the only things changed with these original models was a switch from 2D to 3D analysis to reveal total loss; and a switch from the ground offered to free space. I look forward to Cecil, once again, impeaching his own evidence (and typically without once mentioning the data).

I am sure I have sunken to new lows and once I am exposed for what I am (an English major), vindication will taste sweeter than wine. (may as well steal that thunder too)

Hi All,

Being one to never leave too many unanswered questions (Cecil merely
questions questions); I poured 100W into the original model (the only
change made was from constant I/E to constant P).

In fact, the proximity of ground allowed 99.38 watts to be absorbed by
the load!

How much reaches the load once this dead horse wrenches free from
ground's death grip and is allowed to ascend the stairway to heaven?
0.4982 watts

You heard it here first. ;-)

And, yes, another change (2 total) was made to the ground offered to
make it, instead, free space.

Who knows, maybe the "traveling wave" model is for a new matching
device for greater load efficiency. Unfortunately it would be best
suited for 80M speakers.

Kraus already did it for us. Note the relative phase
graph.

http://www.w5dxp.com/krausdip.jpg

The phase shown on my Standing Wave Current graph is
the phase relative to the source phase. For a pure
standing wave on a 1/4WL wire, the standing wave current
phase is everywhere equal to the source current phase.
That's why it cannot be used to "measure" the delay
through a wire or through a coil.

Hi Dan,

The trick with cygwin is that the interface you connect to first, and
download, is a package manager. Once you have that installed, you
then need to run it and select the right packages - mostly X11 and
XFree86.

Welcome to _Nix.

You are wasting your time. The entire purpose of the model
is to illustrate the phase shift in the traveling wave
current - absolutely no other purpose.

So how do you explain the phase shift in the current which
is obviously traveling wave current?

So instead of sweeping technical facts under the rug,
you hide them in a black box. In both cases, the only
apparent purpose is to maintain ignorance.

It seems that whatever part of the system you don't
understand, you draw a black box around it so you
don't have to understand it.

So I ask you once again, given the following two stubs:

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2

--43.4 deg 600 ohm line--+--46.6 deg 600 ohm line--open
Vfor1-->|-->Vfor2

What are the phase shifts between Vfor1 and Vfor2 for
the two cases?

I am dead serious. You need to think about this a bit more.

Why would something "referenced to the source phase" change when that source itself was changed? This is no different than the elementary example of walking in a train car. One's speed relative to the seats does not change simply because the train is traveling at a different speed on the rails.

What does your IEEE dictionary say about the meaning of "referenced to"?

Hi Steve:

I had one in the past. As in all antennas they receive like they transmit. The performance of the antenna varies with the frequency. At 10MHz it's very narrow and its gain is a good bit less than a dipole. At 28MHz it's very similar to a dipole and in the middle of its range slightly less than a dipole.
Like all antennas the performance varies with how high it's above the ground and with the compact loop there is one other slight problem. When the antenna is mounted horizontally it must be at least 20' to 30' above the ground. Mounted horizontally it is Omni directional. If it isn't mounted that high it must be used with the loop vertical. In this case it can be as low as 3' and still work but it will be directional. It will have nulls at right angles to the loop and have its best response in the plane of the loop. In mine I could get a very good SWR over the whole range but at 10MHz the 2:1 SWR range was about 5KHz and became wider as I went up in frequency to about 100KHz at 28MHz. This SWR bandwidth also applied to the receive signal levels. If I tuned my receiver away from the low SWR point the signal levels dropped by large amount. This is a very usable antenna if you are one who sets in a small range of frequencies, like maybe a net operation, it is a frustrating antenna if you like to tune around a great deal. There is one maybe useful feature of the narrow tuning. It may be a quieter antenna just because it acts as a high Q band pass filter in front of radio and may help on a noisy band with a not so good radio.

Cecil,

Interesting comment, especially since you frequently reference
s-parameter analysis.

A direct quote from AN-95-1, the slide version, is:

Two-port, three-port, and n-port models simplify the input / output
response of active and passive devices and circuits into "black boxes"
described by a set of four linear parameters.

If you deny the legitimacy of "black boxes" do you need to give up the
use of s-parameters?

In my EZNEC examples the source current reference
phase is zero and all the currents at the various
points are referenced to that zero source phase.

If the source current phase is changed, the phase
of all the currents at the various sampling points
change.

In TravWave.EZ, the current is sampled by a zero
ohm load in segment 10 of the wire.

Source phase Seg 10 phase
0 deg -47.82 deg
-10 deg -57.82 deg
+10 deg -37.82 deg

The current in Seg 10 is clearly referenced to the
phase of the source and obviously lags the source
phase by 47.82 degrees.

Thank you, Gene. That contradicts what you said before
about the black box not being allowed to have two of
the four terminals on the other side. Play silly games
with the facts and you tend to get caught.

> If you deny the legitimacy of "black boxes" do you need to give up the
> use of s-parameters?

No, you need to give up your assertion that a four-
terminal black box doesn't have two terminals on
the other side. Your black box and HP's are two
entirely different concepts.

HP puts a black box around a 4-terminal network to
enhance understanding of the contents of the black
box. You put a black box around a stub to promote
ignorance of the contents of the black box.

I have said before. Specify that the black boxes be
supplied with the four measured s-parameters stamped
on them and I can probably tell you which box is which
without even applying a signal.

Or, more logically, forget the black box entirely since
it is totally irrelevant to the subject being discussed.

Exactly what is it that you think you have proved by
using black boxes. Please be specific.

Isn't that exactly what I said? What you are showing above is the change with respect to some arbitrary point, not with respect to the source.

The antenna current phase does not change at all wrt the source.

I said no such thing about "black boxes" being unable to have more than
two terminals. What I said is that the "black boxes" defined by Keith
and Roy have only two terminals.

If you want to drift off into some other irrelevant chatter, go right
ahead. It might make you feel good, but it won't change the real world.

That's my argument and appears to be the opposite of
what you have been saying.

The antenna current phase is referenced, i.e. relative,
to the source phase. Are we using different definitions
of the word "referenced"?

Please provide your definition for "referenced".

Let me say the same thing in a different way. The
difference between a particular antenna current phase
and the source current phase is fixed no matter what
reference phase is chosen for the source current.

But the "black boxes" defined by me have either two
terminals or four terminals. Here they are again:

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open

--43.4 deg 600 ohm line--+--46.6 deg 600 ohm line--open

--43.4 deg 600 ohm line--+--j567 impedor

The black boxes are drawn around the '+' point just as
I said before. That makes the first two examples four-
terminal networks and the last example a two-terminal
network.

Now tell us again how s11, s12, s21, and s22 are identical
for those three black boxes.

As if imaginary black boxes exist in the real world. :-)
Get real, Gene. Any black box you provide, I can open.

Cecil,

I am sorry that you seem to be having so much trouble with the English language today. 8-)

If the antenna current was referenced to the source current, the reported antenna current phase would *not* change when the source phase was changed. As you can see, the reported antenna current phase *does* change in step with adjustment of the source phase. This means that both sets of phases are referenced to the same arbitrary point, not directly to each other.

This was exactly what Roy was saying, followed by your challenge of his understanding of NEC.

My definition of "reference" is the ordinary definition found in scientific and technical writing. It is the equivalent of "relative to" used by you above.

This gives a whole new meaning to "referenced". The
antenna currents are phase-locked to the source current.
That's about as good a reference as one can get - being
phase-locked. You, like Richard C., are obviously just
pulling my leg.

>
>Let's look at the "traveling wave" model and see what it has to offer
>in the cold harsh light of reality.

Well first, mea culpa's to the readership in using Cecil's models
(never a good idea as they did not attend the question he introduced
whereas mine did). However, moving on to the nut of my copping a
plea. I had not noticed that Cecil drove his wires into MiniNEC
ground - something I have never done in all my modeling. So, my
"changes," as reported, were faithful, but very much unbalanced the
implicit return path through that MiniNEC ground.

Being the good analyst, I then considered my previous work in an even
colder, harsher light of brutal reality. What I did was to replace
that ground path with a wire symmetrical to the 60 footer and then
raised the assembly an inch.

>Right off the bat with its performance: -23.74dB
-42.04dB
>What could possibly account for all this loss? The "load?"?
And through a follow-up last time, the same conclusion. The
transmission line apparent load for a 100W constant power consumes
99.25 watts

>Instead of tossing the load, let's toss ground and put this corpse in
>free space. It's performance: -0.30dB
-42.20dB

>center stage has now been nailed to the floor with no more total
>variation than 2.15 degrees. Hard to imagine how a transmission line
>could so thoroughly rape its inventor.
The current is still not constant (the original model must rely on a
poor return path to accomplish this). The phase does vary by 90
degrees.

As modified, the current slope reveals this is no longer a traveling
wave antenna (but it never was anyway). This can be remedied by
shifting the last load (the apparent transmission line load) to 750
Ohms.

This, of course, improves nothing in performance.

>Turning to the "standing wave" model, would it be instructive how a

>long ago.

Well, after sifting my own tea-leaves (one has to wonder how this
escaped the intrepid author's scrutiny) - no not much difference after
all. Transmission lines are pretty robust when designed correctly.

However, neither bear any resemblance to the original post's mention
of rhombic or dipole antennas; and my models of those clearly discard
Cecil's confusion over his named currents by using conventional

designs of conventional antennas. After all, who ever heard of a traveling wave transmission line? [This is probably the only point Cecil could ever hope to argue as he would immediately seize on the opportunity to force that term into the canon.]

>***** Irony meter pegged *****

Gene is of course correct. Perhaps the difficulty with basic concepts such as phase reference is part of the reason why Cecil finds it necessary to invent and promote his alternative theories.

A moment's thought would reveal one good reason not to reference phase angles to "the source" -- NEC and EZNEC allow multiple sources, each having a phase angle chosen by the user.

This is simply a diversion to deflect the discussion away from the sticky questions about "electrical degrees" which his theory is unable to resolve. Phase reference is another, and we can expect more.

Duhhhhhhhh! When you changed the conditions, you changed
the characteristic impedance. The reason for your confusion
is obvious below.

> This, of course, improves nothing in performance.

This is not a performance issue. This is a current phase
issue. The purpose for the existence of that EZNEC file
is to illustrate traveling-wave current - nothing else.

> After all, who ever heard of a traveling wave transmission line?

Who indeed? Richard, FYI, a transmission line terminated
in its characteristic impedance *IS* a traveling wave
transmission line. Do you understanding the meaning of
a "flat" transmission line? A flat transmission line *is*
a traveling wave transmission line. Here is one modeled
in EZNEC. Download and click on "Load Dat".

http://www.w5dxp.com/stub514R.EZ

Why is the ignorance level about traveling waves so high
on this newsgroup? It's the result of those inadequate
lumped circuit models.

That's true, but the discussion so far has been about single
source systems. What is the phase reference when a single
source is used. You say it is not the same as the source
so exactly how much does it differ from the source default
of zero degrees? What does the reference default to if not
the phase of the source signal.

Is the reference phase a user selectable option? If so,
how do I select and change that reference phase without
changing the source phase?

I strongly suspect, based on my 20 years of user experience,
that the reference phase defaults to the source phase in a
single-source system. I personally have never set the
reference phase to anything except the single-source phase.

Roy Lewallen wrote:
> This is simply a diversion to deflect the discussion away from the
> sticky questions about "electrical degrees" which his theory is unable
> to resolve. Phase reference is another, and we can expect more.

There were no black boxes in the original example so the
black box was the original diversion. Coming back from that
diversion, can you calculate the current amplitude and phases
in the original example? I would be very surprised if you
could do it. I would be even more surprised if you did it
and published the results. Roy, here's your chance to nail
me to the wall. Simply prove that the phase shift between
Vfor1 and Vfor2 below is something other than 36.6 degrees.
(All of Roy's worshipers hold their breath for a response. :-)

This is not "my" theory - this is standard distributed
network reflection theory that I learned at Texas A&M
in the 50's. And the theory is certainly capable of
resolving the electrical degree problems.

Here's the original example again - no black box necessary.

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2

Assuming 100v at 0 deg incident upon the open at the
end of the stub, what is the phase shift between
Vfor1 and Vfor2?

Vfor2 = 100v at -10 deg
Vfor1 = 143.33v at -46.4 deg

The phase shift between Vfor1 and Vfor2 is 36.6 degrees just
as predicted originally. Roy, you are always advising me to
use voltages so I did. The results are easy to verify if you
know how. But I don't think you know how.

Everyone is invited to use any valid model you want to and
prove me either right or wrong.

I predict that Roy will be silent on this subject and rely
on his political power to try to suppress those results.
The emperor has no clothes. The emperor's worshipers have
no clothes.

Source record: 31175

Tom Donaly wrote:
> Cecil's decanter has too much lead in the glass.

Tom, why haven't you calculated the phase shift from
Vfor1 to Vfor2 in the following example?

--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2

Assume that 100v at 0 deg is incident upon the open
at the end of the stub.

I get
Vfor2 = 100v at -10 deg and Vfor1 = 143.33v at -46.6 deg.
Looks like the phase shift is 36.6 degrees after all.
Please feel free to prove me wrong.

Of course it does, Richard. The rhombic is a traveling-wave antenna. Unlike a 1/2WL dipole, its current phase changes with distance from the feedpoint.

We certainly have an EZNEC 1/2WL dipole model but I don't think EZNEC comes with a rhombic model. Do you happen to have one? If not, I'll be glad to whip one out. I guarantee the results will be no different from the 1/4WL terminated wire that I presented previously.

I've just discovered that this "copy" from the ARRL
>>The ARRL Antenna Book, 20th edition, page 13-13.
must be quite a departure from reality. In outer space?

Well, I trust Cecil hasn't mislaid his glasses once again, performed another math error, or tried to use his car keys to get into the house; but when we substitute his former 1/200th wavelength above ground, this antenna clearly exhibits a SWR of 1.33.

Of course, it can be jimmied back into outer space in an effort to suppress evidence of standing waves, but like the Ghost of Christmas Past, those chains will still rattle poor ol' Cec'. (Will he give Cratchit the day off?)

Cecil's clever crafting can always be mined for simple problems. Pay dirt every time.

Now that I have been exposed for what I am, I can full well expect a lump of coal the size of West Virginia in my stocking. I'm going to need a larger mantle. :-(

No, it is a perfectly normal technique to test a theory or model. The black box reveals just enough information to solve the problem, and nothing more.

In this particular case, the impedance at the terminals of the black box is the only *necessary* information to solve the transmission-line problem (in the steady state, at one frequency). It is not necessary to know how that impedance was created.

Conventional transmission-line theory handles this situation effortlessly, thus proving that no more information is needed. Any theory that claims to need more information has failed the test - for somewhere it has a soft centre that means it cannot be trusted.

Professional scientists and engineers are quite ruthless about this. They don't wait for other people to propose such tests - they do it themselves, beating hardest on their own ideas, to find out what they're good for and where the limits are. Any ideas that don't stand up to this treatment are ruthlessly discarded.

That isn't always easy, but a professional scientist or engineer has to have the clarity and integrity to know when it has to be done. That is why the professionals are very careful not to keep ideas as pets. As in farming, it's only the amateurs who can afford that self-indulgence.

Try a non-electronic example. If all the dimensions on my
house are referenced to the left front corner, when I move
the left front corner (along with the rest of the house),
none of the numerical values change.

If the dimensions are referenced to the fire hydrant, all the
measurements change by the same amount after the move.

This is your opportunity to demonstrate that you are not
like your "gurus" who never admit mistakes.

Or we could have a fun discussion about Mulroney who
recently said ""The most difficult thing in life, I think, is to
admit one's mistakes . . . ". Clearly Mulroney is not like
the rest of us who make enough mistakes that we have
plenty of practice admitting them. Oh wait. Maybe he
makes them, but just refuses to admit them. Hmmmm.

Black boxes have their function but I doubt that any proponent
of black boxes will admit that the function proposed here is
to obscure technical facts because those technical facts are
distasteful to some people.

Ian, the entire problem (as stated previously by me) is to
ascertain the phase shift at the impedance discontinuity
between Vfor1 in the 600 ohm line and Vfor2 in the 100 ohm
line at point '+' in the following example. That is the
problem as stated. It's a straight forward problem - no
black box necessary.

```
--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2
```

Assuming the voltage incident upon the open end of the stub
is 100 volts at 0 degrees, I calculate the following voltages
at point '+'.

Vfor2 = 100 volts at -10 degrees

Vfor1 = 143.33 volts at -46.6 degrees

The phase shift between Vfor1 and Vfor2 is 36.6 degrees.

You should be able to prove or disprove those values. In
fact, you seem to be frothing at the mouth wanting to
disprove them. Well, go ahead and prove me wrong (if you
can).

Instead of performing the calculations to disprove my figures,
you attempt to sweep part of the problem under the rug by
putting everything from point '+' to the end of the stub in
a black box thus making the stated problem impossible to solve.
I'm sorry, but that is an unethical diversion away from the
stated problem.

I have already stated that no matter what is in the black box,
if the impedance or impedor is -j567 then the conditions external
to the black box are identical. But that diversion has nothing
to do with solving the original problem.

Why are you afraid to solve the problem as stated? I am going to keep repeating this posting until someone provides a solution to the original problem.

My voltage calculations above are either right or wrong. If they are wrong, as you suggest, please prove it. If they are right, I don't blame you for trying your best to suppress the technical facts by hiding things in a black box but now the whole world is aware of your attempted suppression of technical facts, not a good reputation to have for a technical editor.

OK, what is the *reference interest rate* for an
adjustable rate mortgage? An ever changing prime
rate?

References do not have to be fixed. I was using
the EZNEC source current as the reference. I rarely
ever change that current away from the default
value of 1 amp at 0 degrees.

> This is your opportunity to demonstrate that you are not
> like your "gurus" who never admit mistakes.

I freely admit that the definition of "reference" that
I was using is different from the definition that others
could choose. It was a mistake not to better define the
word before I used it. However, I did state that I was
using the EZNEC default current as my reference and
nobody objected to that statement at the time.

Here's a request to anyone capable of performing the
necessary math. Can anyone verify or disprove my
two voltage values in the following example?

Shortened Stub Example:

rho = -0.7143
--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2 Vi-->|
Vref1<--|<--Vref2

Assume the RMS voltage, Vi, incident upon the open
end of the stub is: Vi = 100 volts at 0 degrees

At point '+' 10 degrees back from the open,
Vfor2 = 100 volts at -10 degrees
Vref2 = 100 volts at +10 degrees

Vfor1 = 143.33 volts at -46.6 degrees
Vref1 = 143.33 volts at +46.6 degrees

The phase shift between Vfor1 and Vfor2 is 36.6 degrees.

The phase shift between Vref2 and Vref1 is 36.6 degrees.

The total RMS voltage at all points up and down the line
is 200 volts at 0 deg.

For current phase, EZNEC does not display the same
absolute phase as the "Load Dat" function reports.
That would appear to be a bug in the EZNEC GUI
software.

I'm glad you asked that question. Perhaps W7EL can tell
us why EZNEC does not display the same current phase as
it reports in the "Load Dat" function. EZNEC seems to
display the current amplitude correctly but it is unclear
exactly what EZNEC is displaying when the current phase
box is selected. That's why I used the "Load Dat" feature.

Here is a graphic using the "View Antenna" window for
the EZNEC files TravWave.EZ and StndWave.EZ.

http://www.w5dxp.com/eznec.jpg

Looking at TravWave.EZ with the current phase turned
off, the current displayed is indeed the amplitude of
the current up and down the wire which is essentially
a constant RMS magnitude.

But with the current phase turned on, the display does
not display the same phase reported by "Load Dat". It
displays a cosine function when the actual phase function
is a straight sloping line varying from 0 degrees at the
feedpoint to -90 degrees at the load resistor. What
EZNEC is actually displaying associated with phase
is unclear, confusing, and misleading.

StndWave.EZ has the same unclear display for phase.
The current amplitude is the correct cosine function
but the current phase is misleading. The "Loads Dat"
function says the phase varies from 0 degrees at the
feedpoint to -0.11 deg at the open end of the wire,
i.e. virtually no change at all in phase up and down
the wire. Yet EZNEC displays a cosine function for the
current phase the meaning of which is unclear.

To answer your question, EZNEC does not display phase
when the current phase box is selected. It is unclear
to me exactly what EZNEC is displaying when the current
phase box is selected.

You do get a *graphic* record of the current amplitude in
the "View Antenna" window. It is unclear exactly what
is displayed when the current phase box is selected.

You do NOT get a numeric record in the View Antenna
window. For a numeric record, you must use the "Loads"
and "Load Dat" feature.

Hi Jimmie

I dont know what MTB is, so this reply might be worthless to you. I have built decent "coax relays" using TO 5 relays enclosed within copper with BNC connectors. Your application may require better performance than mine. But, the relays are so inexpensive that it might be worth trying to fabricate one and try it. I can send you pictures of the last one I made if you have interest in building one.

Jerry

$250 is cheap..

BUT.. I suspect that the isolation of the circulator isn't high enough (typically, 25-35 dB, depending on how narrowband the device is). Maybe, though, with the Tx being a few milliwatts, the receiver can tolerate -30dBm into its input port?

What's the isolation requirement?
How about loss in the "on" state?

What about a diode switch? At 440MHz there are lots of diodes that would work, and for milliwatts, you just jam a bunch o'current through it to turn it on hard, so it's way up into the conducting region.

or a FET?

Or, for milliwatts, what about any of the readily available CMOS video switches? The venerable 4066 probably isn't going to work, but

Or, one of the nifty GaAs switches out there. Mini-Circuits has a raft of them. I've used the RSW-2-25P.. DC-2.5GHz, about 1 dB insertion loss, handles +20dBm, 45 dB of isolation at UHF. $3 each

If you want one in a connectorized package: the ZYSW-2-50DRhas 45 dB of isolation, 1dB loss, and runs about $60.. includes the TTL driver. Will handle 10mW wihtout too much trouble.

3645. The pursuit of the all band antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-20 17:03:23 UTC
From: art <aunwin@insightbb.com>
Message-ID: <54dae60c-eb24-4a45-b2bf-469ad745256f@p1g2000hsb.googlegroups.com>
Source record: 31112

It can be seen that a fixed radfiator hasd a primary frequency and
then some harmonic frequencies.
The spacing and the resonant points of an antenna resides in the
amount of resistance in the cuircuit
from zero upto a critical point as with a tank circuit. This
resistance value has the action of bringing the radiator
vibrational amplitude to zero where it then takes of to a diminishing
value compared to other componenents in the circuit to the point that
where the radiator is resonant the contained resistance has negnigable
effect.
Thus one can make a folded dipole with a variable resistance in the
radfiating circuit such that the main resonant point can be determined
as well as the spacing between the harmonic frequencies.
In addition, if the radiator consists of increased induntance designs
such as contra windings then the distance between the resonance point
and the harmonic points begin to decrease.
Thus using the above one can now make a all band antenna where the
resonance points line up with the desired frequencies.
An easy way to accomplish this is to wind wire on a dielectris from
end to end and back again several times
until one has wound at least two wave lengths on the former and then
feeding the arrangement at the beginning and ending wire points. Using
a mfj 259 one can then determine the spacings of the resonant point by
stretching the windins as well as adding the required variable
resister. Note. the resistance absorbs the energy between
resonance points and diminishes in effect as the point of resonance is
aproached. For more understanding of the radiation format of radiators
review the circumstances of voltage overshoot with respect to tank
circuits
The above will provide an alternate discussion thread that will take
away the current tunnel vision aproach
with respect to "black boxes" and bring the newsgroup back to the
advancement of antenna techniques if it is that that peeks one's
interests.

By the way, it is the ELECTROMAGNETIC field that launches the
particles from the radiating surface and it is the MECHANICAL REACTIVE
FORCE that provides the mechanical resonance of the radiator WHICH
JOINS THE THEORIES OF NEWTON AND . MAXWELL that Einstein struggled for
in vain.
For those that feel that mechanical laws of Newton cannot be used with
respech to electrical subjects(ala Roy) here is a chance for you to
prove your point.

Diode Switches on the end of 1/4wave Stubs work really well up to
the 25 Watt Level. You could make one of these really cheap, out
of RG174U and a couple of Hot Carrier diodes.

But Ian,

Suppose the box is labeled -j567 ohms.

Then I ask, "at what frequency is this impedance -j567?".

I find that the impedance for -j567 ohms is 4 Mhz.

Now I take a length of 600 ohm VF = 1 transmission line and vary the
length until I am at resonance with whatever is in the black box at 4
MHz. Resonance would imply 90 degrees total phase shift.

My measurement shows that the length of 600 ohm line to cause this
effect is 43 degrees.

Assuming my measurement is correct, doesn't that tell us a little more
about what is inside the box? It isn't just "any" -j567 ohm impedance
that can cause resonance with a 43 degree 600 ohm line. It is probably
not a discreet capacitor, it would likely be some sort of transmission
line or something that that has 10 deg length, correct?

With a few more measurements, we can determine the Zo of the
transmission line that "appears' to be in the black box, correct and
essentially verify that it a transmission line. We should be able to
both measure and calculate Zo.

If we choose our independent measurements carefully enough, we should be able to define exactly what is in the black box with only 2 terminals.

I agree you need more than a smith chart (which was where I made my mistake before).

art,

Wideband antennas already are available with no need for the "tank circuit/equilibrium" concepts, design methods and limited band segments you think must apply.

The link below describes one: a commercial HF antenna that has essentially the same radiation pattern from 2-30 MHz with an SWR less than 2.5:1 without a tuner, and is nearly 100% efficient throughout that range.

Not too usable for most hams, but that will be due to economic and real estate issues, not to the (real) laws of physics.

In all versions, the View Antenna display shows the currents only graphically and not numerically. There are three ways to find the numerical value of current at a particular segment:

1. Click the Currents button at the left of the main window. This gives the currents at all segments.
2. Insert a zero ohm load at the segment of interest and click Load Dat to see its current.
3. Insert a zero volt voltage (not current) source at the segment of interest and click Src Dat to see its current.

It's not what I believe, Ian, it is what you did right
here in front of God and everybody. There was absolutely
no reason to introduce a black box concept unless you
were trying to hide something embarrassing inside the
black box. That embarrassing something is obviously
the phase shift at an impedance discontinuity which you
are trying your best to suppress.

>> but now the

Hi Arthur,

Newton's law:
F = M ï¿½ A
these FMA terms are:
F is force in Newton;
M is mass in kilogram;
A is acceleration in meter / second / second.

We can compute the force on a 10 meter long, 10 kilogram antenna
accelerated by earth's gravity field:
F = 10 kilogram ï¿½ 9.8 ï¿½ meter / second / second
or (reduced):
98 kilogram ï¿½ meter / second / second

When we add 100 Watts of power (for however long), it is clear that
Mass doesn't change. Or perhaps you can tell us how much.

When we add 100 Watts of power (for however long), it is clear that
Acceleration due to gravity doesn't change. Or perhaps you can tell
us how much.

There are only two variables to find Force in Newton's laws. How much
does 100 Watts change Mass or Gravity? I really don't expect you can
answer that because it is too simple: one or both numbers provided
above will be different, that is all. Can you give us something as
specific as I have? In other words, for 100 Watts applied to a 10
meter long, 10 kilogram antenna, will its Mass change to
11 kilogram
or
9 kilogram?
Or will gravity change to
9 ï¿½ meter / second / second
or
8 ï¿½ meter / second / second?

Only one or two very specific numbers have to shift here. Can you
tell us which or how much? This is, after all, your topic, your math,
your profession, and your chance to prove your point.

This IS a log periodic design which provides for close segments of
resonance
limited only by the number of elements aplicable for a frequency
spread.
I not only THINK that limited band spread applies, I KNOW for sure
that it does
when considering impedance changes with respect to frequency.
This operates on the same principle of multi elements of different
lengths as
opposed to a mechanically lengthened radiator presently on sale for
amateurs.
You are dwelling too much on old teachings in a book that was around
when you
were young. The next generation will leap frog you as newer books with
fresh
concepts are printed. This will give lie that all is known about
antennas!
The antenna I described does the same thing while mounted on
the
top of the tower where consideration of ground plane is not an issue
and where
TOA can be varied by tilting, the latter becomming increasingly in use
in
present day communications.
Your education in radiation tho limited is commensurate with your
age and
experience,certainly not up to par for the future generation but
enough to
satisfy your particular life expectancy segment.

Hi Dan,

Why not prove your measurement is correct?

You already know the reactance. Plot it on a Smith chart for your line (that is what makes Smith charts useful). Does your 43 degree rotation lead to resonance?

Contrariwise, put your line at resonance on the Smith chart for your line and rotate 43 degrees, do you land at the black box's terminal reactance?

If you are adding more operations than either ONE of these two, then you are working hard at finding the wrong answer and doing your measurement incorrectly.

Hello, Roy and all. Every unmoderated science newsgroup I've lurked in always has one or more individuals that seem to delight in bucking conventional science wisdom even in those cases where experimental evidence completely validates the predictions of applied mathematics. (Gosh, what ever happened to cold fusion?) One guy regularly complains that respected physics journals won't publish his papers. Of course he imagines there's someone or some agency out to get him, never considering other reasons for his rejection. Perhaps on usenet he acquires some validation.

Hey, people are free to view nature and its processes however they choose but if they want others to view it that way it takes more than "Because I say so." Especially to a roomful of skeptics. Of course I'm also reminded of the hornet's nest that Marilyn vos Savant stirred up a few years back in academia with the "Monty Hall" problem. (Turned out she was right after all) The truth always emerges eventually. Theories often have to be modified as new discoveries occur.

Are you sure I can't interest you in an energy-saving power factor correction capacitor for your home/ham shack? How about a broadband dipole with a feedpoint VSWR < 1.6 over the contiguous 2-30 MHz band? Sincerely, and 73s N4GGO,

On this newsgroup, John, it's the gurus who are bucking
conventional science with such concepts as:

1. There's no phase shift at a Z01 to Z02 impedance discontinuity
in a transmission line even though the applied mathematics says
there is. Black boxes are quickly introduced to hide the phase
shift from the unwashed masses.

2. There's no difference between
I*cos(kx)*cos(wt) and I*cos(kx+wt)
i.e. between standing waves and traveling waves even though
the applied mathematics graphs are completely different.

3. Standing wave current can be used to measure the delay
through a loading coil even though applied mathematics says
the standing wave current doesn't change its relative phase
anywhere in the 1/4WL antenna from feedpoint to tip.

4. Reflected waves contain zero energy and therefore cannot
deliver energy back to the source even though applied mathematics
says that ExB is the power density of that reflected wave.

5. EM energy can just "slosh around" inside a transmission line.
It doesn't have to travel at the speed of light even though it
is made up of photons which applied mathematics tells us
cannot slow down.

6. The EZNEC graph of traveling-wave current phase contains
a 64% error yet the author says there's nothing wrong.

John, would you care to comment on those six points?

Hello, Cecil, and I think Roy and others have provided valid comment. I would like to recommend, in addition to the ARRL publications, the Schaum's Outline on transmission lines. I don't know if it's still in print but it was authored by Chipman. Like the other paperback Schaum's Outlines it is not intended to be an in-depth examination of RF transmission line theory (if you want that I would recommend King and Harrison's book). Chipman's book, OTOH delves into the theory at a level that IMHO doesn't require an EE degree to comprehend. There's also loads of practical problems worked out (lots of stuff on incident, reflected and standing waves). I think it would prove timely to pursue sources besides r.r.a.a for your electromagnetics training. Sincerely,

All multi-band antennas are a compromise. The only "all band antenna"
that exists is an isotropic radiator.

Bob, I've had the book for 30+ years. I'm not kidding about
those six items. Those are the old wives' tales being spread
by about six of the gurus on this newsgroup. I learned this
fields and waves stuff back in the 50s from Ramo, Whinnery,
and Johnson and some good professors at Texas A&M.

In particular, how about taking a look at my math on
the thread titled "Please verify (or disprove)". I would
welcome anyone proving me wrong but so far, there are
zero takers.

No, you can't. if the frequency is fixed, is sinusoidal, and steady state,
then every box that measures -j567 ohms is perfectly equal. that is the
whole idea of a 'black box' not only can't you tell what is inside, it
doesn't matter what you do on the outside, it will always looks the same.
that is the whole purpose of it, you reduce a part of the circuit to a
single component that has well known performance so you remove that part
from the problem.

BTW, the current plotting error in EZNEC is (100-64)
= 36%.

Do you think a 36% plotting error within EZNEC is nothing
to worry about? Do you think when current phase is displayed
as a sine wave instead of a straight line, that is OK?

If you want to get 'by' then by all means read all the technical books
that reflect the times, that makes you a follower.
If you want to go beyond the books then you have to do the research
and
that makes you a leader. If you place your research in front of a
panel
of experts in the field and then get accepted, it then has a place in
future books thus providing a stepping stone for those that follow.
This newsgroup is for followers of present day books.

By the way, "no" does not equate to "cannot" in any language
It only equates for those who wish to jump the Grand Canyon in two
strides.

If the goal is to measure the phase shift at an
impedance discontinuity in a transmission line, why
would someone deliberately put the impedance discontinuity
inside a black box? That defeats the goal of measuring
the phase shift.

not worth responding to art... but this statement is incorrect. an
isotropic radiator doesn't have to be 'all band' or even wide banded.
'isotropic' says nothing about frequency dependence at all, only about
directivity.

No.
This group is for book followers. I have placed it in front of a
panel of my peers consisting of professors knoweledgable in the field.
You are welcome to follow the descriptions/instructions that I have
provided over the years if you have an ounce of inquisitiveness
but your niche in life is to mock and not enquire.
Go back to the thread of a thousand postings and go around the
circle once more while injecting snakes and ladders that go no where.
Remember, it took you several months to accept that the adition of a
time variable
to Gaussian law results in the same law stated by Maxwell. I haven't
got the time to
provide a thread of a 1000 postings to satisfy anybody that takes that
long to absorb
every step into new territory absent a book.
Art

> line or something that that has 10 deg length, correct?

No, that's not correct. As I've said several times before, you can't tell anything about the contents of the boxes by doing measurements at a single frequency, except to determine the terminal impedance at that frequency. No matter what kind of test you do (at that one frequency at which the impedances are the same), you cannot distinguish among them. You can't tell which box is which, or detect anything about them which is different. If you have a theory which predicts otherwise, you should investigate where the flaw in the theory is. If you're not convinced, simply describe in detail the tests you would do and the numerical results you expect to get for the different boxes. Anyone with a background in transmission line theory (which include several regular group participants) will be able to tell you what results you should expect from your tests, which will be the same for all the boxes. And several of us are also able to make decent measurements as well as provide equations to show why. That's how engineering is done.

> With a few more measurements, we can determine the Zo of the
> transmission line that "appears' to be in the black box, correct and
> essentially verify that it a transmission line.

Not if you measure only at the one frequency. Not only can you not tell the Z0, you can't even tell if it's a transmission line at all. It might be a capacitor, a complex LC network, or some combination of transmission lines, capacitors, and inductors.

We should be able to
> both measure and calculate Zo.

> If we choose our independent measurements carefully enough, we should
> be able to define exactly what is in the black box with only 2
> terminals.

It's a bit frustrating to continue posting the same thing over and over and see continued claims that the boxes can be distinguished. We'd both save a lot of bandwidth if you would, instead of just claiming that you can do it, show that you can. Even theoretically -- describe the tests you would make and the results you would expect which would be different for each box. Then we'd have something which could be discussed objectively.

> I agree you need more than a smith chart (which was where I made my
> mistake before).

Yes, I'm afraid you'll need a lot more.

Let me reiterate that the contents of the boxes can certainly be distinguished with tests made at multiple frequencies. But the objective of my comments has been to counter the claim that there's some terminal property such as "electrical degrees" which the various lines (box contents) have which is different at the single frequency at which their reactances are the same. I hear this claim still being made, but so far not any evidence to support it. When such evidence (not including typical Cecil-style hand-waving, but real numbers) is presented, I'll be glad to point out where it's in error.

Hi Arthur,

Then you don't have anything to offer, do you? What a mooch.

**** IRONIC CONTENT FOLLOWS *****

Let's try this theory on for size.

Arthur, I have an antenna the size of a pin head that works 160M with
20 dB gain, when I operatered it from my basement. It uses the
Earth's magnetic lines of force to penetrate soil, rock, and
constructions. By using ultraminiature plates at right angles, the
Poindexter Vectrod takes on a helical twist that steers through
electron orbits to escape the resistorance of nucklei (wich everyone
nose is 100,000 times larger) thus reducing gain by 5 or 3 divisions.
It is provened by Faradsay laws which came before Gus the mangetic
plumber patended the north and south poles.

If you cannot prove this, then goe and warshipyour old dead gods and
put bernt oferings at there feeet because nonething isreally none but
low so eventhough fo' you to go say you no it, it no so - whoa! so
woe, how po'.

I provided the evidence in the thread titled,
"Please verify (or disprove)". You have yet
to respond to it. Here's your chance to nail
me to the wall for good, Roy. Why are you so
silent on that thread?

OK Roy, here's your chance. From the previous example:

```
--43.4 deg 600 ohm line--+--10 deg 100 ohm line--open
Vfor1-->|-->Vfor2 Vf-->|
Vref1<--|<--Vref2 Vr<--|
```

Given Vf = 100 volts at 0 deg.

Vfor2 = 100 volts at -10 deg

Vref2 = 100 volts at +10 deg

Vfor2 = tau1*Vfor1 + rho2*Vref2 = 100 volts at -19 deg

Solving for Vfor1 = 143.33 volts at -46.6 degrees

Vref1 = rho1*Vfor1 + tau2*Vref2 = 143.33 volts at +46.6 deg

Note that the two above equations are equivalent to
the s-parameter equations:

b1 = s11*a1 + s12*a2 and b2 = s21*a1 + s22*a2

OK but if you can measure Zo of whatever is in the box, then you know the length by virtue of it being -j567. It should only take 2 terminals to measure Zo.
Knowing Zo, then I can normalize the smith chart and directly read the electrical length in degrees. True, it would help to know that the box contains a transmission line.

But I am only trying to find out what is in the box so it is a mental
exercize. I know it is a transmission line, open, and the impedance at 4MHz
is -j567. If Zo for example were 100 Ohms, then -j567 would correspond
to -j5.67 on a smith chart normalized to 100 ohms and it is 10 degrees long.
What electrical length corresponds to -j567 if Zo measures 200 ohms? 300
ohms? They will all be different right?

Although one can get a current amplitude plot vs length
from EZNEC, it seems impossible to get a current phase
plot vs length. That's probably why so many people are
confused. Click on "Currents" and transfer that data
to EXCEL to make things a lot clearer.

The "other side" will not allow you to assume a transmission
line. The "other side" will not even allow you four terminals
on your black box. The entire purpose of the black box, in this
present context, is to confuse and confound the unwashed masses
so the "other side" can maintain their guru status.

Your math is typically fine (although you messed
up big time with your use of "reference"), when you
allow yourself to use it. It is the interpretations,
conclusions, and allocations of importance that
are flawed.

But now that you have declared black boxes a
conspiracy to hide "the facts", I'm thinking maybe
you should go join the MI5 guy.

Anyway, along the way you learned (or maybe
already knew and just articulated) that the effect
on the 600 ohm line is the same regardless of
the content of the black box producing -j567,
and for the black boxes, the phase shift at the
terminals is undecidable. And since the problem
can be solved without this information, it is also
irrelevant.

A bit of progress.

...Keith

Space Weather News for Dec. 20, 2007
http://spaceweather.com

URSID METEORS: Earth is heading for a stream of comet dust that could produce a pleasing outburst of "shooting stars" this weekend. Forecasters say dozens of meteors per hour could emerge from a spot in the sky near the North Star (Polaris) when Earth encounters the dust on Saturday evening, Dec. 22nd. These meteors are called "Ursids" after Ursa Minor, the constellation where the North Star is located. If forecasting models are correct, the shower's peak will occur between 2100 and 2200 UT (4-5 pm EST) with meteors visible as much as four hours before and after that time.

The source of the dust is Comet 8P/Tuttle, which is traveling through the inner solar system this month and next. The comet itself can be seen through binoculars not far from the radiant of the shower. This gives sky watchers a rare opportunity to see a comet and its meteors in the same observing session.

Ursid meteors, which appear in small numbers annually, have a reputation for faintness and delicacy. Dark skies are usually required to see them; bright moonlight on Dec. 22nd will only exacerbate the problem of visibility. However, say forecasters, during an outburst of Ursids there may be a fair number of bright meteors. No one knows what will happen--all the more reason to look!

Visit http://spaceweather.com for sky maps and more information

Cecil,

I presume that this is a silly question, but "Did you read the manual"?

EZNEC is displays the current phase exactly as described in the manual.

Hint: Current is shown as distance from the axis. Current PHASE is shown
by a rotation around the axis, not by the distance from the axis.

Aha, so you agree that there is a 36.6 degree phase
shift between Vfor1 and Vfor2? That is certainly
progress. Now if you can only convince the gurus.

> But now that you have declared black boxes a
> conspiracy to hide "the facts", I'm thinking maybe
> you should go join the MI5 guy.

I didn't say all black boxes are a conspiracy to
hide the facts. But consider that when the goal
is to measure the phase shift at an impedance
discontinuity and someone insists on putting the
impedance discontinuity inside a black box where
the phase shift cannot possibly be measured, then
that person desperately wants to keep the results
from that measurement from being known.

> Anyway, along the way you learned (or maybe
> already knew and just articulated) that the effect
> on the 600 ohm line is the same regardless of

There was never any argument there so that statement
is just a straw man - go ahead and knock it down and
get it over with. Nobody disagrees with you.

> and for the black boxes, the phase shift at the
> terminals is undecidable. And since the problem
> can be solved without this information, it is also

The phase shift at the impedance discontinuity *CANNOT*
be solved without information about the impedance discontinuity.
Exactly what is it that you are so afraid that someone is
going to discover? The technical facts? You already admitted
that my calculations were accurate and valid. What more could
you possibly want to hide?

So I cannot display current phase vs length? No wonder
Roy is so confused about the nature of current phase.
Seems I have to paste the current phase into EXCEL
just to get a decent graph of it.

If indeed!

>What electrical length corresponds to -j567 if Zo measures 200 ohms? 300
>ohms? They will all be different right?

Of course, any one of an infinite number of different possible contents could reside within the box; but you don't know which one is inside the box unless you look.

This reminds me of an argument I had with a Chief Boatswain's Mate when I challenged him that "you can't make a horse drink water." His (like Cecil's) solution was:
"You hold his head under water and suck on his ass!"

I hear this particular solution has been used to solve an unrelated problem: a way of curing chapped lips (it keeps you from licking them).

The better part of the members here use chapstick.

Sounds like it would work, to me, but if it were me I would use wire instead. You can probably place wire more effectively in your attic and just use an SGC antenna coupler to tune it at the feedpoint. Would probably not only work better, but would be cheaper, too.

I didn't write anything about the word equating. I added words to it.

Dave K8MN

I don't recall reading anything about your level of education
in things RF. I seem to recall you are a retired mechanical
engineer dabbling with things RF in your spare time.
It seems fairly obvious to me that your education in radiation
can't even deal with the present tense, much less the future.
I would strongly consider this before braying like a jackass
to every person you talk to that *does* have an education in
things RF.
But it is possible that if you do that, you will lose much of
the entertainment value that you provide. :/
So go ahead.. Make our day with even more RF bafflegab.
Like I once said, you make the EH antenna guy look fairly
sane by comparison. :/

Dear All,

I have some beginners questions regarding antennas:

*** Why is it difficult to design and construct HF transmit antennas
for high power PEP, compared with low power 100 W?
Conceptually what is the difference between the two in design,
material construction?
Why do people find the high power harder to design and construct?

*** I understand that omnidirectional antennas transmit in all
directions with almost equal gain. Is it hard to design HF antenna
with directional gain in one direction and minimum in other
directions?
How is this done(conceptually): electrical length, material
contruction?

*** HF wire antennas: can these be for high power transmission and
directional gain (guess the would always be omnidirectional)?

*** How is angle of transmission with the horizon (elevation)
controlled in a HF antenna ?

*** Can receive antennas also be diectional or are they always
omnidirectional receiving from all sides?
Do receive antennas have power ratings?

Thank you

Vijay

Who says they find it harder to design for high power? The *design* is exactly the same for high/low power. Only the *implementation* is different. With high power, you will have greater current or voltage which will require a larger conductor or greater insulation. Example: A dipole fed with ladder line. The typical ladder line sold for ham use will break down (arc over) at around 1200 volts (IIRC). On some frequencies, the impedance of the antenna will be quite high. By Ohm's Law, E(voltage) = I(current) X Z(impedance). If the antenna has, say Z=2000 ohms and due to running high power, you have an amp of RF current flowing, you will have 2000 volts (1 X 2000) which will exceed the breakdown rating of the ladder line. Please read the ARRL 'Antenna Book'.

> *** I understand that omnidirectional antennas transmit in all

Very briefly, several ways: multiple phased vertical antennas or a Yagi antenna will give you directionality. Please read the ARRL 'Antenna Book'.

> *** HF wire antennas: can these be for high power transmission and
> directional gain (guess the would always be omnidirectional)?

Yes, there are directional wire antennas, for example the Sterba Curtain or Rhombic. For high power, you would use the appropriately rated insulators and feed line. Please read the ARRL 'Antenna Book'.

> *** How is angle of transmission with the horizon (elevation)
> controlled in a HF antenna ?

Too complex to explain here. Please read the ARRL 'Antenna Book'.
>
> *** Can receive antennas also be diectional or are they always
> omnidirectional receiving from all sides?

Antennas are 'bilateral'; that is, if they are directional for transmit,
the same characteristics apply for receive. Please read the ARRL
'Antenna Book'.

> Do receive antennas have power ratings?

No.

The above answers are *very* basic and don't even scratch the surface of
antenna design. The questions you ask above would require a book to
answer properly. Oh, did I mention that you should read the ARRL
'Antenna Book'? If not that, at least read the antenna chapters in the
ARRL 'Amateur Radio Handbook for Radio Communications'. (www.arrl.org)

It is very simple.

Voltage.

The higher the power the higher the voltage.
100W into 75ohms gives 86V.
200W @ 75 Ohms = 122V
500W @ 75 Ohms = 196V
1000W @ 75 Ohms = 273V

The current also goes up with power.

Higher voltage mean heavier duty construction.

The voltage show are at the terminals of a simple dipole.
The voltages at the ends of a dipole will be much higher.
Receiver antennas don't have power ratings.

Although the local 146.76MHz repeater has 5W from a
collocated FM BCB at the diplexer input.

The "National Electric Code" has some requirements
for receive antenna conductor size that no one bothers
with. I don't have my set of NEC rules handy, but the
wire size was picked for mechanical strength rather then
power handling capacity.

Terry

The best all band antenna I used was in my novice days... A 100 watt light bulb on the end of a pair roughly 33 foot wires strung up through a tree... Worked a dozen states one afternoon on 15 and 40, then worked the locals on 80 that night... The Knightkit T-100 loaded up just fine on that all band antenna... I don't think it was isotropic, but it sure did blink when being keyed.. The neighbors came over wondering why it was Christmas in September.... That was cycle 19... What a great time we had...

> At point '+' 10 degrees back from the open,
> Vfor2 = 100 volts at -10 degrees
> Vref2 = 100 volts at +10 degrees

It appears to me that you have the signs wrong above.
The voltage at the joint will be a wave later in time than
the one at the open end so it should have a greater
angle, i.e. plus.

Except for that, the computation seems correct,
though you have not explained your work.

> Vfor1 = 143.33 volts at -46.6 degrees
> Vref1 = 143.33 volts at +46.6 degrees

This step has no explanation. Can you provide a justification
from first principles? Since the reference is still the open
end, you need to show that jumping across the joint
results in a 36.6 (I use your numbers) degree phase change.
Then you can compute 46.6, not the other way around.

First principles would be the rules for voltages at an
impedance discontinuity and the expressions for summing
sine waves. Please state any other assumptions you make.
It would also help if you made exactly clear what information
is needed to compute the phase shift. Just rho? What else?

Next, what are the useful properties of this computed
phase shift. Does it facilitate the solving of problems?
Which ones? Is using the computed phase shift an
improvement over the conventional ways of solving

the problem? Or is the computed phase shift just
an alternate way of viewing what is happening? If the
latter, does it have any downsides? Does it mislead
in any way? Will it cause the student to assume
something that will have to be unlearned later?

> The phase shift between Vfor1 and Vfor2 is 36.6 degrees.

Silly math error? 36.6 + 46.6 +10 -> 93.2, which does not
align with your previous posts.

> The phase shift between Vref2 and Vref1 is 36.6 degrees.
>
> The total RMS voltage at all points up and down the line
> is 200 volts at 0 deg.

I don't follow this statement. Which line? From the original
experiment, is not the total voltage at the driven end zero?

...Keith

Humph, all this hot air just addles my aged brain...

I do know a FEW things however...

I know that standing waves exist because I can slide my fluorescent bulb along the line and show precisely where they are

I can measure the distance between peak voltage points with a metric wooden ruler and demonstrate/prove that 3X10^6<meters> / F<cycles> = the length of the measured 2 radians of travel....

But most importantly I KNOW that the standing waves are real and have energy because my fluorescent tube lights up as it passes the peaks... That requires energy/watts/joules to flow through the gas of the tube...

You can use all the damned words in the world to talk around and obscure the subject, but when I slide along my line the bulb lights to maximum brilliance every half wave length of the standing waves...

But what does it mean at the other places along the line where
the bulb does not light?

Does it mean that there is no energy at these points on the line?

Most hams use one screwdriver antenna with various
lengths of counterpoises.

I believe you are correct but since |Vfor2|=|Vref2| the
math turns out the same if consistency is maintained,
which it was.

> Except for that, the computation seems correct,
> though you have not explained your work.

I'm wondering how many people on this newsgroup can do
that computation that you say "seems correct".

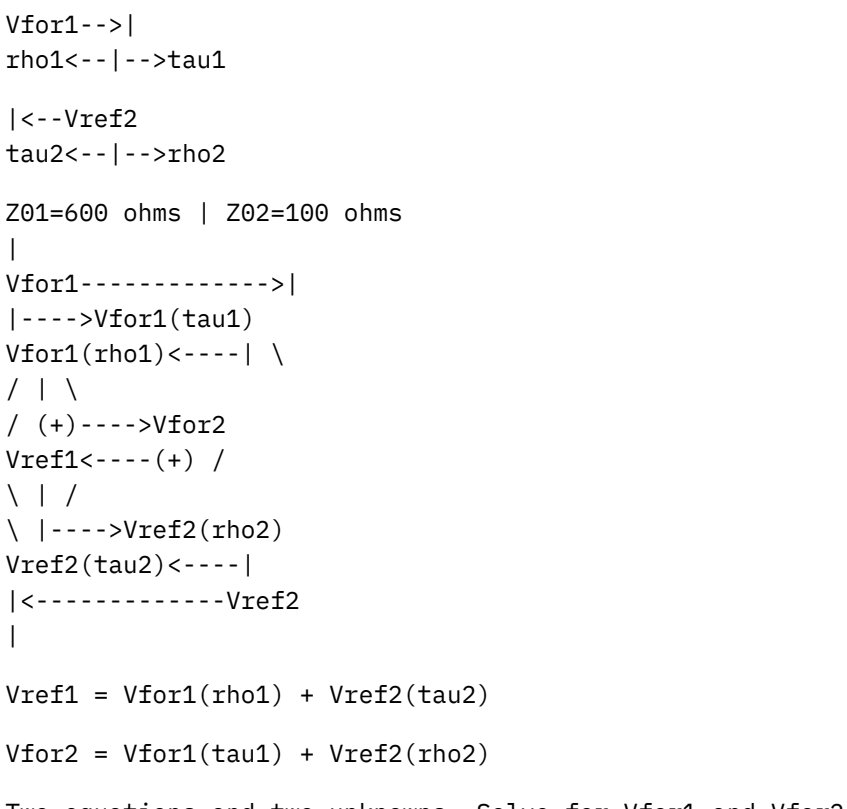
>> Vfor1 = 143.33 volts at -46.6 degrees
>> Vref1 = 143.33 volts at +46.6 degrees
>
> This step has no explanation.

Yes, because I wanted independent verification. Do you
know how to do the math? If so, see if you get the same
values that I did. Everyone else is also invited to perform
the math. It's pretty simple reflection superposition stuff.

> Can you provide a justification from first principles?

I did that in another posting but I will repeat it here.
Here's the voltage superposition diagram. In fixed font:

Component Voltage Diagram



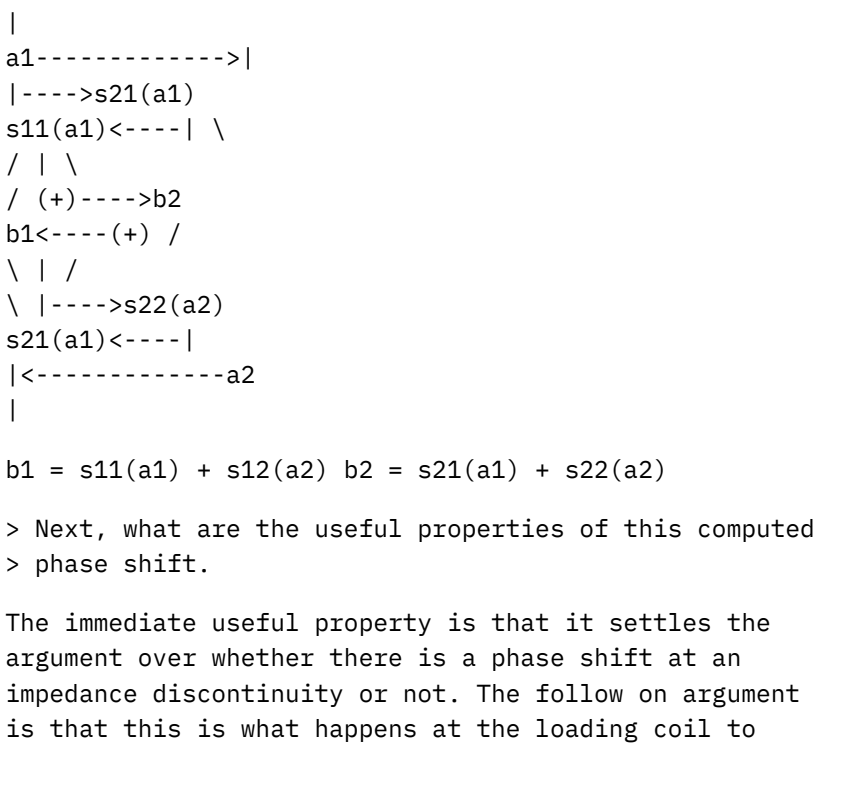
Vref1 = Vfor1(rho1) + Vref2(tau2)

Vfor2 = Vfor1(tau1) + Vref2(rho2)

Two equations and two unknowns. Solve for Vfor1 and Vfor2

Or if you prefer s-parameters:

s-parameter diagram



b1 = s11(a1) + s12(a2) b2 = s21(a1) + s22(a2)

> Next, what are the useful properties of this computed
> phase shift.

The immediate useful property is that it settles the
argument over whether there is a phase shift at an
impedance discontinuity or not. The follow on argument
is that this is what happens at the loading coil to

stinger impedance discontinuity in a base-loaded mobile
antenna, i.e. it's related to the phase-shift-delay
through the loading coil. It will eventually explain
how loaded mobile antennas really work and may (or may
not) point to some improvement that can be made.

>> The phase shift between Vfor1 and Vfor2 is 36.6 degrees.
>
> Silly math error? 36.6 + 46.6 +10 -> 93.2, which does not
> align with your previous posts.

Where did the 46.6 degrees come from? The 600 ohm section
is 43.4 degrees long. 36.6 + 43.4 + 10 = 90 degrees.

I remember where the 46.6 degrees came from.
43.4 + 46.6 = 90 degrees. 46.6 degrees is the electrical
length of the 600 ohm line needed to complete the 600 ohm
1/4WL stub function. But that was a different example.

>> The total RMS voltage at all points up and down the line
>> is 200 volts at 0 deg.
>
> I don't follow this statement. Which line? From the original
> experiment, is not the total voltage at the driven end zero?

That was a pre-coffee brain fart from a canceled posting. It
is a false statement. I changed that sentence, in the subsequent
posting, to something like:

At point '+', Vfor1+Vref1 = Vfor2+Vref2 = 196.96v at 0 deg.

The phasor diagram of that equation speaks volumes and is
something you previously asked for. I will draw it up and
post it on my web page.

Ofcourse not!.
The energy is directed else where, it usually changes to heat.
As I have stated before, in a tank circuit the resistance in the
circuit
also is cyclic with respect to energy distribution. Where there is
resonance
the resistance factor is quite small. As one moves to the "near
stable"

position the resistance factor becomes larger with respect to energy distribution.
If you wish to pursue what is happening in such a circuit then break up the application
of voltage in consequitive steps to see the rotational effects of capacitor and
inductance energy discharge together with the energy distribution when the
voltage drop over the energy storage units are equal.

Somebody has beat you to it. Theories, like advice, are free so they
exist everywhere. At least this one has some math (though fallacious)

behind it:

See:

http://www.allanstime.com/UFT_private/final2.htm

The Fundamental Field Equation

The following equation is fundamental in understanding how the force fields interact and come together for this new unified field theory:

D = (E/c*G)/A2*

where D is the relativistic density, E is the energy of the unified field, c is the velocity of light, G is the universal gravitational constant, and the last part of the equation, / A2*, will be explained below. D and E are tensors with eigenvalues and quantum states associated therewith.

*"A2" should read "capital Pi, sub-2"

Density Dependence, D
The density D is the dependent variable; changes in the energy (energy flow in and out of a region) cause changes in the density. For example, the energy flow to and/or away from any space-time continuum along the diallel lines determines the corresponding change in the density in that space-time continuum. Appreciating the energy field at the particle as well as in a region is central to the understanding of this theory. The energy can come from any of the force fields. For example, both equations apply: E = mc2, where m is the relativistic mass and E = hv, where "h" is Planck's constant "v" is the electromagnetic frequency of the photon.

Energy can come from the other force fields as well. Later we will see some spectacular and very important examples of this interplay of the force fields.

Parallel Component (A2)
A dimensional analysis of the above equation reveals that A2 has dimensions of length, time and mass as the force fields interact. The forward slash "/" denotes being parallel in the unified field theory's mass-space-time continuum along the local diallel lines. The "sub-2" on the "A" denotes the energy coming in or going out in the mass-space-time continuum along the diallel lines in the local environment or region.

Combining the energy with this term we have E/Pi2. Hence, we see that this denotes the energy per mass, per length and per time taken in the parallel direction of the local diallel lines. The quantity in the denominator of equation(1), cG, is the normalizing factor, so that the dependent variable, D, is the density factor taken in the parallel direction of the diallel lines. It is the density that is the principal resultant output after combining the energy from the force fields.

Since the subscript "sub-2" denotes the energy from all sources coming into or going out of the local environment or region, a "sub-1" is implied for the energy, E, and the resulting density, D, as the recipients of the net energy coming in along the diallel lines into the environment or region.

I suppose someone has written on the topic before. But is that like a
crime in this group?

I suppose a person might with a lot of effort to synchronise the
screwdrivers, and a whole heck of lot of money for the screwdrivers
themselves, manage to put a really mediocre antenna in their attic!

There are a lot more cost effective solutions out there.

But what does it mean at the other places along the line where
the bulb does not light?

Does it mean that there is no energy at these points on the line?

...Keith

Fluorescent bulb or neon bulb respond, are fired, by voltage being higher.
Where the voltage is high, the current is low and vice versa (standing
waves).
Energy is the same along the antenna, just standing waves exhibit max and
min according to distribution of current or voltage along the radiator.

If W8JI, W7EL and their followers moved neon bulb along the loading coil,
they would see the change in brightness along the coil (getting brighter
closer to the top) indicating diminishing current along the same length.
Ergo (standing wave) current is not constant along the loading coil as they
tried to convince their followers to the contrary.

73 and Merry Christmas to all

One can just look at the standing wave current equation and
tell it is not constant. The standing wave current varies
with location on the antenna.

The main hang up in the trend to alternate aproaches to Newton such as
the relatavistic aproach is the inability to bring gravity into the
picture
based on the laws of Newton, and without gravity one cannot have a
unified
theory which is the holy grail of today. The theory provided presented
nothing
that combined electro magnetic forces with those of gravitation. The
article
presented provided two theories both of which depend on the other and
without
connection to any known principles of science. Thus without a solid
starting
point based on known science there cannot be a meaningful review and
would
never be accepted as such.(The theory has not qualified for a review
as yet)
My aproach is based on existing laws where equilibrium and gravity is
inherrent which is a solid starting point to provide a trail that
connects
to electro magnetic fields (the stated parameters for a unified
theory
which presently has not been achieved). The mathematical trail is so
simple
it is somewhat audacious in that by adding a time varient to a law
that is
based on gravity and equilibrium per Newtonian terms we have found a
direct link
to the laws of Maxwell. But that really is not the pot of gold !It is
the trail
rules with respect to equilibrium that provides the advances in

science which
shows that a radiator can be of any size or shape or elevation pattern
but also
an array of such elements which, being in equilibrium, requires just
one feed point
thus obtaining gain over any other array while occupying a smaller
volume.
So theories are fine but if you cannot use them in actuality to
provide an
advance in science then they are just words without justification.
I am comfortable with my 160 meter antenna on top of my tower that has
no
equal with respect gain versus volume occupied, all of which is a
direct
derivative of the law of Gauss.
The same goes for the resonant points which is the subject of this
thread
since it also duplicates the tank circuit around which the connection
of
gravity and magnetic fields exists. By doing this the universal theory
is again given a morsel of reality with respect to existing laws.
Everybody have a merry Xmas. And try not to be overbearing to those
gathered around you
Art

That isn't quite the concept. The claim that we're testing is that, at
the one frequency where all of the mystery boxes have the same
impedance, you will not be able to distinguish between them using
steady-state measurement techniques. Therefore we have to tell you what
that frequency is (if we let you find it out for yourself, using
variable-frequency test equipment, we'd all be stepping outside the
agreed rules).

So the labels on all the mystery boxes already say "-j567 at 4MHz", and
that will be the only frequency at which you can make measurements.

My point (and Roy's, and Dave's, and that of any textbook author) would
be that there is categorically no way to tell these boxes apart by means
of a steady-state impedance measurement at 4MHz.

To tell them apart, you would have to do something *else* - for example, make more measurements at other frequencies, use time-delayed reflectometry, or pry the boxes open.

>Now I take a length of 600 ohm VF = 1 transmission line and vary the
>length until I am at resonance with whatever is in the black box at 4
>MHz. Resonance would imply 90 degrees total phase shift.
>
"At resonance with" is not the right concept; see below.

>My measurement shows that the length of 600 ohm line to cause this
>effect is 43 degrees.
>
>Assuming my measurement is correct, doesn't that tell us a little more
>about what is inside the box?

No. You have indeed confirmed that this particular length of this particular type of line is one of the myriad possibilities for what *could* be inside the mystery box. But you haven't added anything to your information about what actually *is* in there.

>It isn't just "any" -j567 ohm impedance
>that can cause resonance with a 43 degree 600 ohm line. It is probably
>not a discreet capacitor, it would likely be some sort of transmission
>line or something that that has 10 deg length, correct?
>
Not correct - you have jumped to a conclusion about things being "at resonance" with one another. All we're saying is that the impedance has the same *value* at a given frequency. That doesn't imply resonance in any way.

Would it help if I confirmed that one of the boxes genuinely does contain a discrete capacitor of... what would it be, 70.17pF? No, it wouldn't help at all, because there is still no way you could tell which one it is, without stepping outside of the agreed rules.

>With a few more measurements, we can determine the Zo of the
>transmission line that "appears' to be in the black box, correct and
>essentially verify that it a transmission line. We should be able to
>both measure and calculate Zo.
>
>If we choose our independent measurements carefully enough, we should
>be able to define exactly what is in the black box with only 2
>terminals.
>
At one single frequency, there aren't any "independent" steady-state measurements that could help you (independent of what?). As Roy says, whatever methods you propose will not hold up to detailed examination, because it fundamentally cannot be done.

The fundamental point is that impedances of the same value can always be substituted for one another, and at a given frequency there is no steady-state measurement that distinguish between them. That

substitution principle is what allows us to use a dummy load to make tests on a transmitter, and it forms the basis for impedance bridges and most other forms of impedance measurement.

Yeah, Mike. That was my take, and the reason I suggested wire
antenna in attic with an antenna coupler/tuner up there.

You have to put them in a black box and see if you can measure the impedance
discontinuity.

I think you might be on to something, Art. I believe gravity is at
work, lowering the radiation angle of my big tribander.

Why, Merry Christmas, Art. Those gathered around me (not because of
gravity, but because of common affection) will be quite safe as long as
none of them expounds on crackpot antenna theory.

Better yet, you can increase the ignorance level even farther
by prohibiting anyone from applying a signal. Then even empty
black boxes cannot be distinguished.

Methinks a field strength meter will distinguish between
a dummy load and an antenna. :-)

No. I am just a retired mechanical engineer which puts me at the
bottom of the totem pole with respect to most subjects,
especially physics and radiation where we have a large
amount of experts in those fields residing on this very
newsgroup.
I do have Plank's lectures and an assortment of fields and waves
type of thing plus the normal radio and electrical engineering
reference books and ofcourse many of the Terman books
which I imagine is normal for most G.E. engineers who worked
in the industrial controls area. Today I worked on repairing
a 50 inch plasma set for a change thus getting away from antennas.

Hi Dan,

I see you can field questions on gravity where Arthur faltered.
Perhaps you can respond to:

>tell us which or how much? This is, after all, your topic, your math,
>your profession, and your chance to prove your point.

It seemed to be a very simple question at the time. There are only two variables and if Arthur is right about Newton, then one of them must change when we add power. In fact, if Arthur is right about gravity, it can be the only variable that changes - the question then becomes: How much? Given gravity is one of the weakest forces in the Universe, then adding 100W to it should peg the meter. One has to wonder how that went unnoticed in 120 years of transmission - especially with some of those Megawatt LW stations.

If you can't help him, then you can join us in a very long line that Arthur has just stepped into, deep at the back somewhere outside the fire door, down the alley, around the block a couple times, and disappearing into a side street in Keokuk, Iowa (you two might run into Mitt Romney there).

>I have an RF body and a few HF slugs, what I dont have is a Bird
> microammeter. I am trying to find data that will let me calculate the
> power from just knowing the DC voltage output from the RF body.
>
> Jimmie

First of all you will have to terminate the slug DC output on a resistance equal to that of the Bird meter, which is 1,440 ohm. If you do not do that, the slug would not have the proper load and the DC voltage variation with RF power would not match that of the Bird meter scale.

To calculate the DC voltage produced by the slug when you apply the full-scale RF power, you shall multiply 1,440 times the meter full-scale current (30uA), so obtaining 43.2 mV.

When you reduce the RF power, the DC voltage variation can be calculated multiplying 1,440 times the current flowing through the meter, which is given by the following expression:

DC current (in uA) = 30 * (-7.378E-12W^6 + 2.547E-09W^5 - 3.407E-07W^4 + 2.248E-05W^3
- 8.188E-04W^2 + 2.692E-02W - 2.749E-05)

where W = power (on a 0-100W scale)

Note: the above relationship is unverified. I found it somewhere (I do not remeber where) and I never tried it.

However, I am not sure whether measuring DC voltage is the best way to proceed, as the voltage values are very low.

You could actually build a meter equivalent to the Bird one. If you can find (not easy!) a surplus meter that has:

- either a 30 uA full-scale current and an internal resistance not higher than 1,440 ohm
- or having a lower full-scale current (i.e. less than 30 uA) and an internal resistance not much higher than 1,440 ohm

it would be easy to transform it into a Bird-like meter, by adding a resistor in parallel (to be trimmed until you get 30uA at full scale) and then a resistor in series (until you get 1,440 ohm).

At that point, profiting of fact that DC meters have a linear scale, you could mark on your meter scale the power values by comparison with a real Bird meter scale. I can help you in that regard, as some time ago I made a scan of a Bird meter scale and I could send you the file via e-mail.

I did that for a Collins wattmeter (for which I had no DC meter) and the result was perfect because the meter I found in the surplus had exactly the the same size as the original Collins meter and I could then simply paste the new scale (printed on paper from a scan of the original meter) on the original scale. In that case however the job was facilitated by the fact that the Collins meter as a significantly higher full-scale current than that of the Burd meter, and it was then not too difficult to find a suitable meter.

Last resource? I am sure you know that on e-bay it is not difficult to find Bird meters stating at 80$ or so.

Nice graphic, Cecil.. But the thread has drifted beyond recognition..
Part of the original dispute <across a couple of threads> as I
remember it, was the contention that there is no energy contained
within the reflected wave and therefore no energy contained within the
standing wave, i.e. a mere artifact...
I simply wanted to point out that the standing wave on a line does
contain energy and it is a childishly simple exercise to prove it,
therefore the reflected wave must contain energy...
As far as the questioner, where does the energy go between the
standing wave peaks - oy vey....
If it is a real question - as opposed to a rhetorical device <which I
hope was the intent> - then the profound ignorance of basic physics is
vastly beyond the limited space I have to go over it... See ANY
introductory level, physics textbook for details...

cheers ... denny

> lengths of counterpoises.

Don Johnson in one of his 1990 books featured a photo of a dipole with two screwdrivers in the 90's. Since hams can build a screwdriver for about $50 each maximum if good scroungers, it's doubtful an SGC tuner is a cheaper or easier solution than said screwdriver dipole.

Such an antenna won't be a great antenna, but then again an indoor stealth antenna is never going to be competitive with full size outdoor antennas well removed from buildings and the like.

I'ld personally rather be on the air rather than arguing the merits of a screwdriver antenna versus an autotuner with wires and counterpoise.

the REAL answer is that the 'standing' wave is a creation of experimenters
100 years ago who didn't have the impedance, current, and voltage
measurement tools we have today, and didn't know of or understand
superposition. 'standing' waves are nothing but a result of superposition
of the forward and reflected waves, they have no physical significance
beyond that. it is worthless to talk about power or energy in them since
they can always be broken down into the component waves which make more
sense to work with.

Can it be done? Sure.
Has it been done? I'm sure it probably has, I've just don't remember
hearing about it.
Would it work? Certainly much better than no antenna at all!
Would it be difficult to build? Just depends on the builder's
imagination and how 'handy' he/she is.
Would there be a commercial market? Probably a small one, with all
the characteristics of a small market.
Are there other ways of going about it? Sure, refer back to that
imagination and 'handy' thingy.

Here is another stealth idea.

My roof is approx 25ft off the gnd, so I was able to run a LOOOOOOOOONG wire from inside of the attic out a window vent, up to the roof and thru a series of TV type screw in standoffs, starting at the peak, up and down the short sides of the roof, along the long sides just above the gutters, and back into the attic. Then around the attic a couple of times. My roof is approximately 30 x 90 feet so all of this is approximately 540 ft long. I also use a auto tuner and a cable isolator (5 or so turns of the feed coax at the base of the tuner), and this works, not the best, but 80m - 2m. I also can switch the configuration from a long loop to a long wire.

Actually, the people who thought about waves 100 years ago knew quite
well about superposition, standing waves, etc. Where did you get the
idea that they didn't?

I find it interesting so many "speak" of gravity as a "pulling force"
when, in all actuality, it is a "pushing force" ...

The earth is like a "bubble" in a "liquid ether", just like a bubble of
air in water, the water is a force applying pressure to the bubble--but
then, it is all how you look at it ...

This is all correct. The ramifications are:

1. Even with increased wire sizes there will most likely be increased losses due to skin effect. You lose effective transmit power.

2. Antenna and transmission line with be dissipating more power due to R losses and heating up. You must design to dissipate this heat or things will melt.

3. Because you have increasing voltages you have to pay increasing attention to terminal spacing and dielectric breakdown in any part of the transmission line or antenna. You might have to do things like round the ends of antenna elements.

4. VSWR becomes more of an issue with higher power. Smaller increases in VSWR can cause dielectric breakdown in some part of the antenna system that under normal circumstances would not be an issue. In other words the antenna system becomes more sensitive to changes that even weather can bring about.

Whoa!
No physical significance?
Like there is no frying the Hustler loading coil from the bottom up (due to standing wave current) or corona flames from the tip (due to high SW voltage) when applying a bit of "worthless" power?

In Einsteins' spirit, let's have a real look at waves (basically the KISS rule):

http://www.colorado.edu/physics/2000/microwaves/standing_wave1.html

you must go to the bottom of each page and click to view the next of the series.

The standing wave is "driven" by the forward & reverse traveling waves, yet best thought of as being "separate in existence" (there are a total of 3 waves!) ... and can only/really exist within strict confines of design--or, resonance ...

But then, this is nothing new, or, you already knew that ... I just like the way this is all presented--on those pages, or, even newbies are introduced to the depth of the argument ...

not due to 'standing' waves... that is due to the superposition of the
forward and reflected waves. They are the real waves, the 'standing' ones
are just figments of your imagination.

Better yet, in a mixer, where two frequencies are combined/mixed to come up with a unique third freq which is then amplified, say to a KW, and used to xmit a signal carrying data--well, this third signal is only a figment of our imagination!

strange ... the power of imagination.

Richard

While gravity is often quoted as exhibiting the weakest force of the four major forces, that force appears to exhibit effects at far longer ranges than the other three. Certain physical theorists have hypothesised that this might be because we only see one aspect of gravity in our three/four (take your pick) dimensional universe. At any substantial physical distance from a point, gravitational force exerted per unit area is generally the largest force observed.

Gravity interacts relatively weakly with matter and even less with the other three forces, so I would expect that any effect would be at the limits of measurement, even with high transmitter powers. Certain 'fringe experimental' groups claim to have found evidence of a reduction in gravitational attraction in the presence of rotating, high powered electromagnetic fields. This would appear to form the basis of proposed 'practical' flying saucer designs by such groups.

Some conventional scientifically monitored experiments have shown apparent slight reductions in gravitational attraction, but whether the effect is real, or the measuring instruments were affected in some way by the presence of extreme electromagnetic fields is a moot point. Most of the proposed designs seem to require rather elaborate and expensive, large structures to be built to create the required fields. I think we can all see where this might be leading...

When the additional 'hidden' dimensions demanded by string theory are factored in, it is entirely possible (even probable) for such effects to occur but not necessarily on a humanly observable scale. Gravity may seem to be the weakest force here on earth, but at cosmic scales it rules supreme.

Yes, it could be that that there are interactions that unify the forces but it may take theories that are not possible to test such as string theory to try to explain them. A theory that cannot be tested is useless. One that involves more than 4 dimensions cannot be harnessed into something of value to humanity. Worse, the interactions, if they are present, exist only in the extremes, such as extremely small interactions when observed on a galactic scale. For all *practical* purposes, the forces appear to be independent but some can have fun discussing strings...Quite useless in real life, in reference to building antennas anyway. Certainly there will never be an answer to Richard's questions, of course he knows that, because any relationship that exists at all, IF it exists, is nearly insignificant (and flakey/stringy). The fact that it may not 'quite' be insignificant, just 'almost' insignificant, will not make any difference to antenna builders in this millenium I'm sure!

In spite of that bah humbug, Merry Christmas all!

Hi Mike,

Without pursuing the other three (you may resolve this in response),
the force of gravity is inversely proportional to the square of the
distance between those bodies being acted upon. This is the same
relation to radiated power (in this case 100W) and the same two bodies
(if we are doing substitutions) if they are located in the far field.

In the near field, the force of radiation varies to the third power,
and in the very close field this power is substantial: if that remote
body is resonant, and in that near field, then it can absorb at least
half of that power or more.

Unfortunately, those who want to hoist Newton's corpse on their
shoulders for a parade celebrating their powers of insight; they
cannot offer that gravity is tweaked even by a thousandth part - and a
thousandth part is easily measured.

>... At any substantial physical distance from a
>point, gravitational force exerted per unit area is generally the largest
>force observed.

This is, no doubt, a reference to nuclear forces where electric and
magnetic dominate in geometries larger than a bacteria. Perhaps
Arthur's levitating particles that dance to RF and leap off the
antenna are fried virii. Unfortunately, for Arthur's levitating
particles, the RF would have to be tuned to several thousand THz.
(Art, a sunlamp would do the same thing cheaper.)

>...Gravity may seem to
>be the weakest force here on earth

I dare say that any subjective test of that would invert the "sense"
of your statement.

>, but at cosmic scales it rules supreme.

The human response aside, at cosmic scales you have cosmic mass in
relation to less than cosmic scale. That is, comparing two galaxies'
gravities is necessarily heavily leveraged with billions of suns, and
yet the distance between the two centers (of galaxies) is probably on

the order of 100's to 1000's of either galaxy's radius. Newton would shrug that off as being unremarkable - still only square law stuff. Newton would probably have expressed the force within 20% on the first pass. Push those two galactic systems to the edges of the cosmos will only reduce that force by the square law (it certainly won't increase it).

However, none of this answers how gravity can be an all band antenna's friend as much as Arthur would like to have them wed.

Can you substantiate the above statement?
My understanding is that it only takes a moderate magnetic field
to levitate a free electron, which is a world of difference
from what you are saying

Unfortunately, that goes against the distributed network
reflection model that I learned at Texas A&M during the 50s.
The joules/sec in any EM wave are ExB. The total joules
stored in the transmission line are exactly the number of
joules necessary to support the forward energy and reflected
energy.

> introductory level, physics textbook for details...

The standing wave current is the phasor sum of the forward
current and reflected current. The standing wave voltage is
the phasor sum of the forward voltage and reflected voltage.

At the point where the standing wave current is equal to zero,
the standing wave voltage is at a maximum indicating that all
of the EM energy at that point is contained in the E-field.

At the point where the standing wave voltage is equal to zero,
the standing wave current is at a maximum indicating that all
of the EM energy at that point is contained in the H-field.

Standing waves are an artifact of the superposition of forward
and reflected waves. Where the two E-fields cancel, the total
H-field will at a maximum. Where the two H-fields cancel, the
total E-field will be at a maximum.

>from what you are saying

Hi Arthur,

The difference is I have experience in the matter, you don't. All you have to go on are books.

Let's just take one very simple example about magnetic fields and electrons: The Magnetron!

Do you know what's in a Magnetron? I doubt it. You will have to look it up in one of your books, whereas I've held on in my hands while servicing a transmitter.

So, already knowing you haven't got a clue about what is in a Magnetron, then I will tell you. Cathode, Anode, and Magnet - nothing else to get in the way.

So, there you have your magnet, and it is whopping big one too with a whopping bloody field that goes waaaaaaaay beyond what you call moderate (moderate is about 12 orders of magnitude toooooo small in comparison!).

Does this magnet rip electrons right out of the metal? It would rip apart the metal first before that happened. And yet electrons fly from Cathode to Anode ONLY when the Cathode is HEATED! What is more, the magnet is utterly unnecessary for those electrons to flow.

Ever wonder why Cathodes (or filaments) are heated? Well, in this case (as in all other cases) because the Magnet doesn't have the oomph to pull the electrons off the cold, cold Cathode. If a magnet can't do it, electrons are certainly not going to jump off an antenna - not unless there is sufficient potential to cause corona. Even then they don't go very far - not even a foot. Corona doesn't measurably add to DX unless you are at sea signaling by semaphore.

Now, can you tell us what a "work function" is? If you could, then this nonsense about levitating electrons would collapse.

I will give you a week to do your research. :-)

this is because there is LOTS of matter in the universe. while each little piece of matter creates a weak field when you add them all up it creates a large field. As a sidelight, there is (at least as far as we know so far) no, 'negative' pole of gravity... that is, every piece of matter equally attracts every other piece. with electric fields or magnetic fields, there are opposite polarities that tend to mask each other (superposition anyone???). so while you could get higher forces with less electric charge, separating them takes more work and the farther away you get the separated charges tend to hide each other so the field falls off faster. it is also hard to clump lots of the same charge together in one place to create a large force since like charges repel each other.

I'd suggest this is a mischaracterization of the contention. I have
seen no disagreement with the notion that the line contains energy.

Assertions about a lack of energy in reflected waves is not
inconsistent with the line containing energy.

> I simply wanted to point out that the standing wave on a line does

Prepare yourself to rethink this connection.

> As far as the questioner, where does the energy go between the
> standing wave peaks - oy vey....
> If it is a real question - as opposed to a rhetorical device <which I
> hope was the intent> -

It was not rhetorical, but an educational question that followed
from the claim. With the claim that a lit flourescent bulb
demonstrates the presence of energy, it is entirely reasonable
to question what a dark lamp means and the original post did
not suggest this understanding.

> then the profound ignorance

There is no need to descend to the level of insult commonly
used by some of the more prolific posters.

> of basic physics is
> vastly beyond the limited space I have to go over it... See ANY
> introductory level, physics textbook for details...

Let us consider a transmission line....

There IS a voltage and current distribution on this line. For
the moment attempt to forget standing waves, travelling waves,
forward waves, reflected waves, ... Just that:

There IS a voltage and current distribution on this line.
These distributions can be expressed as functions of distance
along the line and time:

V(x,t)
I(x,t)

These are the instantaneous real voltage and current
at a particular location (x) and time (t). They can be
measured with a voltmeter and ammeter, though this gets
more challenging at higher frequencies.

Now we know from basic electricity that Power is Volts
times Amps, so we have:

P(x,t) = V(x,t) * I(x,t)

P(x,t) is the instantaneous power at any point and time
on the line. Power being the rate of energy flow, P(x,t)
is the instantaneous energy flow at that point and time
on the line.

If you disagree with any of the above please read no
further and post any objections now.

Good! Agreement.

So let's consider the specific example of sinusoidal
signal applied to a transmission line that is open
at the end. After settling, there is a voltage and
current distribution on this line, but how can we
describe it? Now some of you are immediately
thinking "standing wave", and you'd be right. Its
an excellent description, but we need to look at
the details.

So V(x,t) = A cos(x) cos(wt)
where w is radians/second and x is measured in
degrees back from the open end.

Consider t=0. The spatial voltage distribution
is a sinusoid with a maximum at the open end. As
time advances, this spatial sinusoid drops in
amplitude until the voltage everywhere on the
line is 0, then the amplitude heads towards
minus max. Noting that the zero crossings are
always in the same place and the shape is
sinusoidal leading to the name "standing wave".

From a time perspective, every point on the line
has a sinusoidal voltage, but the amplitude
changes with position. The peaks and zero crossings
occur at the same time everywhere, thus the
claim that there is no phase shift as one
moves down the line.

The current is also a sinusoid, but shifted 90 degrees from the voltage sinusoid, thus there is a current zero where-ever there is a voltage maximum.

Now power is really interesting. Recall that

P(x,t) = V(x,t) * I(x,t)

At certain values of t, the voltage everywhere on the line is 0, so at these times, no energy is flowing anywhere on the line. Similarly for current.

And at certain positions on the line (n*180+90) the voltage is always 0, so the power is always 0 at these points. No energy is ever flowing at these points. Similarly for current at points (n*180).

The sumary, being as pedantic as I can is that "standing wave" is "merely" a description of the voltage and the current on the line. And "merely" is in quotes, because it is a very powerful and useful description, but be careful not to ascribe too much to it. Always keep in mind that the "standing wave" is a description of the conditions on the line, not the creator of those conditions.

Now some of you will be saying "Yes!", it IS the forward and reverse waves that create the conditions on the line. Not so fast. These too are "merely" partial descriptions that when summed, describe the conditions on the line. Very powerful and useful, but again descriptions, not creators.

Some readers overuse forward and reverse waves and start ascribing power to them. These readers think that the forward wave transports energy to the end of the line which is reflected back in the reverse wave. To those readers I offer the following counter-proof....

In the setup above used for "standing waves" it can be seen that there is zero power in the line every 90 degrees back from the open end. At a zero power point, no energy is being transferred. Therefore, the forward and reverse waves can not be transferring energy across these points. Conclusion: forward and reverse waves do not always transport energy.

...Keith

Hi Richard

Art believes that gravity is the force that is holding unbound and by inference, 'neutral' electrons (or possibly some other particle), to the surface of his antenna radiating element. I personally doubt that gravity is the main force involved, but for want of a better description of the phenomenon, I am prepared to continue to let Art describe his antennas as working by this mechanism. It is his theory and as he often reminds us, he is primarily a practical hands on engineer and not an academic. If his antennas work better than anything else of the same dimensions, then someone will eventually arrive at the correct scientific explanation. In the meantime I am content to let him continue to describe his antennas and their workings in terms he understands. It certainly provides for a lot of debate on r.r.a.a.

Cheers

Mike G0ULI

It may not be the 'best' in the world, but if it works, that's the whole point, isn't it? Now you are in a position to tweak, add a 'do-dad' here and there and make it more 'better'. (Another characteristic of antenna building fun!) So, good!

This is where your argument falls apart. you can not apply superposition to power as it is a non-linear relationship with the voltage and current. this is where lots of the arguments on this group begin and get stuck forever. the argument you state in the above paragraph is a contradiction on the most basic level...

take a step back and consider this:

V(x,t)=Z0*I(x,t)
which also must be true at every point on the line for the forward and reflected waves, each taken separately. so you can write equations like:

Vf=Z0*If
and
Vr=Z0*Ir
(i'll leave off the (x,t) for now)
and by superposition you can also do:
V=Vf+Vr
I=If+Ir
Which work just fine if you do fancy graphs and animations to create the

illusion of 'standing' waves along the line. And as long as you keep the two equations separate everything is simple.

BUT, lets look at the a place where the standing current wave is always zero and the voltage standing wave is of course a maximum. if you plug those into ohm's law to find the impedance at that point you get:
Z=V/I (where V is large, and I is zero) so you get an infinite impedance. does this surprise anyone? it shouldn't, this is what the smith chart shows you should happen every half wave along the line. the result of superimposing the waves results in changes in the measured impedance as you move along the line. note this is NOT a change in Z0, that is forever a constant and property of the physical line independent of the waves imposed on it.

So what does this really mean? on the surface it would tend to support the assertion that there is no power flow at the points where the current is zero, and the impedance measures is infinite. BUT there is a catch.

P=VI is a basic representation for instantaneous power at a point given voltage and current, again (x,t) left off but that doesn't matter.
but also you have to keep the relationship:
V=Z0*I
so you can rewrite the P equation 2 different ways:
P=V^2/Z0 = I^2*Z0
now, obviously these have to hold for any wave that exists in the line. so for the forward wave they hold up just fine, and for the reflected wave they hold up just fine.. BUT if you look at the 'standing' wave they fall apart. i.e. for the spot where the current is zero and the voltage is a maximum you get:

P=V^2/Z0 which is a large number
AND
P=I^2*Z0 which is a small number
you can't have it both ways at one point at the same time!

now, what is really happening?
Given:
1. you have 2 waves.
2. these 2 waves are traveling in opposite directions.
3. each of these waves obeys ohms law.
4. the voltage and/or current of these waves obeys the superposition principle.
5. you only need to look at voltage OR current since they are linearly related to each other at every point in each wave.

If you dispute any of the above, do not pass go, do not collect 200$, go back to school and take fields and waves 101 all over again.

Lets think voltage waves for now, this is an arbitrary decision as noted above. and lets consider a lossless line with a short or open end so there is 100% reflection.

So, as these two waves travel along the line they periodically go in and out of phase with each other, there are animations that show this very nicely. lets think about the time where the two waves completely cancel each other so the voltage along the line is zero... did the 2 waves dissappear? no, because obviously an instant later they are back out of phase and the voltage doesn't cancel on the line. is the power zero?? no, since energy can neither be created nor destroyed, it didn't just dissappear, so neither can the flow of energy that is called power. and since we know that when this voltage minimum occurs there is a current maximum in the superimposed waves the power represented by that superposition would contradict the power represented by the voltage minimum... they can't both be correct at the same time!

So what do you take away from this?
1. Standing waves have no physical significance, they do not represent power or energy, they do not obey ohms law, they are ONLY a result of superposition of the voltage and/or current waves in the line.
2. can you measure standing waves? Yes, of course. that is how they got their name, you could measure them and they didn't seem to move on the line. but this is only because simple measurement tools can't distinguish the forward and reflected components that make them up.
3. if you want to talk about power and energy you MUST use the individual traveling waves.

now what does that mean for this lossless line that has 100% reflection??

1. the reflected wave magnitude is equal to the forward wave just traveling in the opposite direction. (voltage and/or current)
2. the power in the forward wave is equal to the power in the reflected wave but traveling in the opposite direction.
3. there is energy stored in the line equal to the sum of the integrated power in the two waves each taken separately. DO NOT sum them first then integrate, that is NOT a legal operation since as has been shown the superposition principle does not apply to power as it is a non-linear relationship!
4. in steady state the net power flowing past any point in the line is zero... that is, there is as much power flowing one direction as the other.

ok, i'm done with my lecture... you guys can now ignore me if you want and go back to your regularly scheduled misconceptions and circular arguments.

> Let us consider a transmission line....

Keith, that was the best example I have ever seen on how
an over-simplified math model can confound and confuse. As
long as one understands the underlying principles, a
simplification can be useful. But when the simplification
is presented as an example of the laws of physics when it
actually violates the laws of physics, it's time to object.
As a useful shortcut, there's nothing wrong with your standing-
wave analysis. It's the conclusions you draw about the underlying
laws of physics that violate the laws of physics.

EM waves must follow certain laws of physics.

1. Being photonic in nature, they must move at the speed of
light at the VF of whatever medium they are in.

2. The power density of an EM wave is ExH in joules/sec/unit-area.
The voltage and current are the *result* of the E-field and the
H-field. In phasor notation: V dot I = E cross H, e.g. adjusted
for the unit-area of the transmission line.

3. The joules in any volume must be conserved. In a lossless
transmission line, joules that have been put into the transmission
line and have not left the transmission line are still in there.

4. EM waves cannot exist without momentum. The momentum in any
volume must be conserved. If EM waves are confined to a volume,
they are moving at the speed of light and reflecting off the
physical boundaries containing the volume.

Do standing waves meet the definition of EM waves?

1. Standing waves do not move at the speed of light. Therefore,
standing waves are technically not EM waves. Standing waves are
a simplified mathematical construct and have no stand-alone
existence outside of the human mind, i.e. standing waves simply
cannot exist without the underlying forward and rearward
traveling waves.

2. Standing waves contain exactly the sum of the energy components
of the forward and reverse traveling waves. The conservation of
energy principle will not allow anything else.

3. The joules contained in the standing waves are exactly the
number of joules needed to support valid measurements of
forward power and reflected power. These joules are supplied
by the source during the transient power-up state.

4. EM waves cannot stand still in a transmission line. Any EM
energy confined to a transmission line must necessarily be moving
at the speed of light in the medium. In a Z0-matched system, where
no reflected energy is allowed to be incident upon the source, all
EM energy confined to a lossless transmission line and contained
in the standing waves must be reflecting back and forth between
two reflection points (physical impedance discontinuities).

About standing waves:

1. The standing wave voltage is not moving. It is oscillating in
place. It is not an EM wave. It's phasor could just as easily
be rotating in the opposite direction and nothing would change.

2. The standing wave current is not moving. It is oscillating in
place. It is not an EM wave. It's phasor could just as easily
be rotating in the opposite direction and nothing would change.

3. There is no net average energy flow in either direction. Therefore,
the net power is zero. Pfor - Pref = 0 However, the forward joules
passing a point in one second are still there and so are the
reflected joules/sec.

The *only* energy in a transmission line with standing waves is EM
energy. Standing wave energy does NOT meet the definition of EM
energy. Therefore, standing waves may be a useful math model but
that model has a built in technical contradiction when forced
upon reality.

For instance, in a one-second long lossless transmission line with
forward power = 200w and reflected power = 100w, the total energy
contained in that line is 200+100 = 300 joules and the EM wave
nature of those 300 joules has not changed because they are allocated
to the standing waves. They are still moving at the speed of light
in the medium, 200 joules in the forward direction and 100 joules
in the rearward direction.

Here is an EXCEL spread sheet of the transient build-up to steady-
state when the steady-state forward power is 200 watts and the
steady-state reflected power is 100 watts in a one-second long
lossless transmission line.

It was a strawman, Dave. The non-linear failures/events
described by Yuri are, by definition, not covered by
superposition which is a linear process. If Yuri had
described the superposed hot spots preceding the non-
linear failures, he would have been entirely correct.

> Richard Clark, KB7QHC

My point is that the element being diamagnetic and generating a
magnetic field
will displace a free electon or particle from it's surface. The force
or magnetic
field, even tho moderate, levitating the particle has a reactive force
upon the
radiator. The succession of these reaction forces puts the radiator
into oscillation
since just like a pendulum there are two discharges of energy per
cycle.
This cycle of events replicate a tank circuit which is well documented
I am not requesting that a large item be levitated but only a small
particle which
by using the parameters put forward by Gauss is now free to remove
itself
from the given arbitary field. These free electrons, of which there
are many,
are so dense that they will appear as a wave as they move away from
the near field
where they search for another diagmatic resting place. If that new
resting place
is also resonant at the same frequency then the impacts will be a
mirror image of
that which created them thus providing a medium for the transfer of
communication.

The laws of the universe are very simple in nature tho experts strive
to make them difficult

Hi Keith,

You are basing this conclusion on the observation that Power = V*I, and because we can not detect V or I at some points in the standing wave, then V*I is zero at these points. Correct math, but wrong conclusion.

What you are forgetting is that power is also found from Power = V^2/Zo and Power = I^2*Zo. More accurately, on the standing wave line, Power = (V^2 + I^2)/Zo. This is why a SWR power meter detects both current and voltage from the standing wave.

This will also be true on the quarter wave stub, which is really 1/2 wave length long electrically, when you consider the time required for the wave to go from initiation to end and back to beginning point. Power is stored on the stub during the 1/2 cycle energized, and then that stored power acts to present either a high or low impedance to the next 1/2 cycle, depending upon whether the stub is shorted or open.

I think you did a very good job in building your theory. It was only at the end (where I think we need to consider additional ways of measuring power) that we disagree.

Hi again Keith,

I would suggest that you add a caveat here. The power equation is true if the measurements are across a resistance. If we are also measuring reactive power (or reflected power), then we need to account for that.

Haste makes waste, and errors as well. The standing wave power
equation is incorrect. It should read "Power = V^2 / Zo + I^2 * Zo"

Sorry for any inconvenience, and for the several postings it will probably stimulate.

Yuri is trying to say that standing waves have real power, they do not. I have shown that in my last big post on here. The one part he properly states is that the effects are due to standing wave voltage. The voltage is indeed real, as i have said. you can measure the 'standing' wave voltage, that has been known for a long time... but the effects are NOT due to power in standing waves.

It appears to be useful that you choose to be anonymous. Otherwise it might be embarrassing.

Rather than all of that handwaving nonsense about Ohm's Law and such, why don't you show us how standing waves fail to satisfy the Maxwell equations?

So what do you take away from this?

Standing waves and traveling waves have equal legitimacy. There are many cases where multiple model descriptions completely capture the physical reality. There is no reason to say that one description is more fundamental than the other.

'standing' voltage and current waves DO satisfy maxwell's equations, ohm's
law, and superposition. you have failed completely to see my point, its
power waves that are the illegitimate children and must be bansished
forever. maxwell's equations are overkill for this exercise, ohm's law and
the simple power equations are all that is necesary to show the

inconsistency, why muddle it with details. after all if you can't understand ohms law and calculate power properly you have no hope of understanding maxwell.

Cecil,

Where do you get so many goofy ideas? Do you have any references at all that support your contention that standing wave energy does not meet the definition of EM energy? I have been in the wave business professionally for about 40 years, and I have read many technical papers, reference books, and text books. I have yet to encounter anything that indicated the inferior nature of standing waves in the energy community.

So you are trying to say that there is standing wave voltage but no standing wave current and therefore no power associated with current???

OK, explain to me where I went wrong.
Back to our standing wave quarter wave coil loaded antenna, aka Hustler 80m mobile whip.
I understand that it is standing wave resonant antenna, with maximum current at the base and maximum voltage at the tip, in between sinusoidal distribution of them. Inserted loading coil exhibits decrease of the current along the coil, diminishing at the top, even if W8JI et other gurus do not believe so.
W9UCW measured the current (standing wave) at top of the coil to be about 40 - 60% less than on the bottom.
K3BU found out that when he put 800W into the antenna, the bottom of the coil started to fry the heatshrink tubing, demonstrating more power to be dissipated at the bottom of the coil, proportional to the higher current there, creating more heat and "frying power" (RxI2). This is in perfect agreement with W9UCW measurements.
So the way I understand it, forward wave is reflected off the tip, reflected wave on the way back superimposes with forward wave, creates standing wave, which at any point can be measured and has current and voltage magnitudes proportional to their position on the radiator.
They seem to be real current and voltage, current heats up resistance, voltage lights up the neons and power is consumed, portion is radiated. The larger the current containing portion, the better antenna efficiency.
Where am I wrong?
I have a hard time to swallow statement that there is no power in standing wave, when I SAW standing wave's current fry my precious coil and tip burned off with spectacular corona Elmo's fire due to standing wave voltage at the tip.
Antenna (quarter wave) radiator is a standing wave circuit exhibiting the above properties, if the formulas say it ain't so......

Merry Christmas to al believers and unbelievers!

Yuri, K3BU

Keith Dsart wrote:
"Therefore, the forward and reverse waves can not be transferring energy across these points."

A wave is defined as a progressive vibrational disturbance propagated through a medium, such as air, without progress or advance of the parts or particles themselves, as in the transmission of sound, light, and an electromagnetic field. Light, for example, is also calld luminous or radiant energy. Sound and radio waves are also examples of energy in motion.

Waves in motion are transporting energy no matter how their constituents seem to add at a particular point.

i am saying that there is standing wave voltage, and standing wave current, but there is no physical sense in multiplying them to calculate a power. hence the concept of standing power waves is meaningless.

>
> K3BU found out that when he put 800W into the antenna, the bottom of the

right R*I^2 makes perfect sense. you are talking about ONLY the current standing wave which makes perfectly good sense. and the R*I^2 losses associated with it make perfect sense. BUT, resistive losses ARE NOT a result of power in the standing wave, they are resistive lossed resulting from the current. remember the initial assumptions of my analysis, a LOSSLESS line, hence there are not resistive losses. If this requirement is changed then you can start to talk about resistive heating at current maximums and all the havoc that can cause.

> They seem to be real current and voltage, current heats up resistance,
> voltage lights up the neons and power is consumed, portion is radiated.
> The larger the current containing portion, the better antenna efficiency.
> Where am I wrong?

again on the voltage, it is exactly analogous to the current above. voltage waves capacitively coupled to a neon bulb are losses and not covered in my statements. But again note, that type of measurement is measuring the peak voltage of the voltage standing wave, and any power dissipated is sampled from that wave and is not a measure of power in the standing wave.

> I have a hard time to swallow statement that there is no power in standing
> wave, when I SAW standing wave's current fry my precious coil and tip
> burned off with spectacular corona Elmo's fire due to standing wave
> voltage at the tip.

YOU HAVE IT RIGHT! the standing wave current causes heating. the standing wave voltage causes corona. but neither one represents POWER in the standing waves.

remember the relationship that must apply within the coax. and can be extended to antennas, though it gets real messy taking into account the radiated part and the change in capacitance and inductance along the length

of the radiating elements.

P=V^2/Z0=I^2*Z0

now remember that you only have to look at one or the other and at all times the relationship in each wave must obey V=I*Z0.

Now consider the infamous shorted coax. at the shorted end the voltage standing wave is always ZERO, by your logic the power would always be zero at that point, but how can that be?? conversly, at a point where the current standing wave is always zero there can be no power in the standing wave, but at that point the voltage is a maximum so would say the power was a maximum... an obvious contradiction.

Art wrote:
"My understanding is that it only takes a moderate magnetic field to levitate a free electron, which is a world of difference from what you are saying."

Moderate fields make free electrons move moderately within and on the surface of conductors.

Electron emission requires more energy than does conduction. Conduction produces a magnetic field which can produce an electric field, etc., etc., etc..

No threshold must be exceeded to produce radiation from an antenna. The weakest received signal must cause at least 50% of its received carrier power to be re-radiated from an antenna of good conductivity.

So we have better than perpetual motion case - we can cause heating without consuming power. I better get patent for this before Artsie gets it! There must be some equilibrium somewhere.

...like, there is standing wave current, there standing wave voltage, but no standing wave and no power in it?

Richard, wake up your english majorettes and snort it out :-)

I know one thing, when standing wave current is high, I get loses in the resistance, wires heating up - power being used.
When standing wave voltage is high, I get dielectric loses, insulation heats up and melts - power being used, ergo there is a power in standing wave and is demonstrated by certain magnitude of current and voltage at particular distance and P = U x I. I don't know what you are feeding your standing wave antennas, but I am pumping power into them and some IS radiated, some lost in the resistive or dielectric loses.

you are SO CLOSE... open your eyes, turn off your preconceived notions and read what i wrote again slowly and carefully.

FIRST remember the assumption was a LOSSLESS line so there are no dielectric or resistive losses. But this is only useful because it makes it easier to see that the power given by V*I in the standing waves doesn't make sense.

YOU ARE CORRECT when you say that the R*I^2 loss is REAL... and YOU ARE CORRECT when you say the V^2/R loss in dielectric is REAL.

Where you lose it is that the V*I for the standing waves is not correct... this is because V and I are related to each other and you can't apply superposition to a non-linear relationship. If you think you have a way to do it then please take the given conditions of a lossless transmission line, shorted at the end, in sinusoidal steady state, and write the equation for power in the standing wave at 1/4 and 1/2 a wavelength from the shorted end of the line.

It appears to me that even with all the successive posts on the subject of power in the standing wave, you all
seem to be missing the ingredient that proves why there is no useable power in the standing wave. It is
because the current and voltage in the standing wave are 90ï¿½ out of phase. Multiplying E x I under this
condition results in zero power.

In addition to another comment above that implies that reflected power is reactive power, this is not
true--reflected power is as real as forward power. The only differences are that they are traversing in
opposite directions, and that while the voltage and current travel in phase in the forward direction, they are
traveling 180ï¿½ out of phase in the rearward direction. Multiplying voltage and current while 180ï¿½ different in
phase results in the same power as when they are in phase.

There's been a lot of confusion between average and instantaneous power. Let me try to clarify a little.

Keith Dysart wrote:
> . . .
> Now power is really interesting. Recall that
>
> P(x,t) = V(x,t) * I(x,t)
> . . .

This is correct. Cecil and others have often muddled things by considering only average power, and by doing this, important information is lost. (As was the case of the statistician who drowned crossing a creek whose average depth was only two feet.)

Roger wrote:
>
> I would suggest that you add a caveat here. The power equation is true
> if the measurements are across a resistance. If we are also measuring
> reactive power (or reflected power), then we need to account for that.

And here's where one of the common errors occurs. The fundamental equation given by Keith does "account for" reactive power. If I(t) and V(t) are sinusoidal in quadrature, for example, then V(t) * I(t) is a sinusoidal function (at twice the frequency of V or I), with zero offset. This tells us that for half the time, energy is moving in one direction, and for the other half the time, energy is moving in the opposite direction. The average power is zero, so there is no net movement of energy over an integral number of cycles. This is what is called "reactive power".

On the other hand, if V(t) and I(t) are in phase, the product is again a sinusoid with twice the frequency of V or I, but this time with an offset equal to half the peak value of V times the peak value of I. What this tells us is that energy is always moving in the same direction, although its rate (the power) increases and decreases -- clear to zero, in fact, for an instant -- over a cycle. The average power equals this offset. So here the "reactive power" is zero. I've described this as energy "sloshing back and forth", which Cecil has taken great delight in disparaging. But that's exactly what it does, as the fundamental equations clearly show.

When V(t) and I(t) are at other relative angles, the result will still be the sinusoid at twice the frequency of V and I, but with an amount of "DC" offset corresponding to the net or average power and therefore the average rate of energy flow. The periodic up and down cycles represent

energy moving back and forth around that net value.

No additional equation or correction is needed to fully describe the power or the energy flow, or to calculate "real" (average) power or "reactive power".

A careful look at what the power and energy are doing on an instantaneous basis is essential to understanding what the energy flow actually is in a transmission line. Attempting to ignore this cyclic movement and looking only at average power can lead to some incorrect conclusions and the necessity to invent non-existent phenomena (such as waves bouncing off each other) in order to hold the flawed theory together.

Space Weather News for Dec. 23, 2007
http://spaceweather.com

MOON AND MARS: At sunset on Sunday, Dec. 23rd, the full Moon and Mars will rise in the east less than two degrees apart. So close together, the two brightest objects in the evening sky look absolutely dynamite. The display will be visible all night long, even from brightly lit cities, and requires no telescope to enjoy.

URSID UPDATE: Observers in Europe report a modest outburst of Ursid meteors last night. The intensity and timing of the flurry is in good accord with predictions that Earth would run into a stream of dust from Comet 8P/Tuttle on Dec. 22nd. Now that the meteor shower is over, attention turns to the comet itself. After a 13.6 year absence, 8P/Tuttle is once again traveling through the inner solar system. At closest approach to Earth on Jan. 1st and 2nd, 2008, the comet, will brighten to 5th or 6th magnitude--a fine target for backyard telescopes and digital cameras.

This:
2. Microwave ovens use standing waves to cook food. This means that
nodes, where the amplitude is zero (where the wave crosses the x-axis),
remain at nearly fixed locations in the oven, and cooking won't occur at
those locations.

From here:
http://faculty.fortlewis.edu/tyler_c/classes/218/lab_microwave.htm

Now, you can argue that any damn way you wish, but "standing waves of no
power" is a myth for idiots!

So let me get this straight:
I describe real antenna situation, which is a standing wave circuit, with
real heating of the coil, which is consuming power demonstrably proportional
to the amount of standing wave current.
You are not answering rest of my argument.
You bring in lossless transmission line to argue that there can not be power
and no standing waves.
I still don't get it.

Sorry, neither is correct.

Z0 is the ratio of V to I of a traveling wave. It's not the ratio of V to I of the total of a forward and reverse wave (which has been carelessly called "the standing wave" in this thread). If you want to calculate power as V^2 / R or I^2 * R, you have to use Re(V/I) as the value of R -- then you will, as you must, get the same result using V * I, I^2 * R, or V^2 / R. As any text can tell you, the value of Z (ratio of V to I) varies along a line which has reflected waves (i.e., has a standing wave). If you use Z0 for the calculation in those cases, you get results which have no meaning or physical significance.

V^2 / R + I^2 * R doesn't give power, using either Z0 or V/I as R. I'm curious as to where that equation came from or how it was derived.

I've always regarded a "standing wave" as being a description of the envelope caused by the interference between forward and reverse traveling waves. But you're saying there are currents and voltages "in" the standing wave. Are you referring to the total current and voltage at any point along the line? If so, why are they always in quadrature? Certainly, the total V and I are in quadrature if the line is terminated by an open, short, or purely reactive load. But not in any other case. Or do you regard a line as having a "standing wave" with its own voltage and current which are different from the total V and I? If so, how do you define a "standing wave"? Are there separate equations for "standing wave" V and I that are different than for total V and I?

I'm afraid you will find that those are the equations for
power associated with a traveling wave. Actually should be
Power = V^2/Z0 = I^2*A0. There is no net power transfer
associated with a standing wave. For a pure standing wave,
V*I*cos(A) = 0 watts.

Walt,

I am trying to make sense of this and the first issue is what you mean by the term "standing wave".

The only meaning that seems possible is that it is the magnitude of the time alternating voltage or current at some displacement along the transmission line.

If that is the meaning, then the situation you describe of 90° phase difference between E and I is rather specific, it can only occur with a distortionless line AND a load that is (s/c OR o/c OR purely reactive).

Is that the case?

If so, should you have stated the assumptions and how does the case you discuss help in explanation of general principles?

>

You seem to be inferring that it is legitimate (in a general sense) to calculate the power of forward and reflected waves as voltage times current (eg Vf*If).

Isn't the instantaneous power at a point a function of time, and it is p(t)=v(t)*i(t) and the expansion of that equals Vf*If-Vr*Ir ONLY when the other two terms of the expansion cancel, and that is the special case of a distortionless line.

Are you illustrating general principles with a special case without stating the underlying assumptions.

Why is it that so many attempts to explain transmission line behaviour, particularly regarding real and imaginary components of power at a point, aren't consistent with basic AC circuit theory?

Owen

I guess the authors of the textbooks never thought anyone
would be so ignorant as to believe that EM waves can stand
still. :-)

EM waves are photonic in nature must travel at the speed of
light in the medium. A standing wave stands still and oscillates
in place. Therefore, A standing wave is not an EM wave - It is
something else, by definition.

That's a false statement. I supported power waves back in
the 1990s. I changed my mind around 1998, almost ten years
ago. I have not supported power waves in this 21st century.
Some other posters on this news still support power waves.
However, I do support EM energy waves.

Oddly, "John", another source tells us:

Another hazard is the resonance of the magnetron tube itself. If the
microwave is run without an object to absorb the radiation, a standing
wave will form. The energy is reflected back and forth between the tube
and the cooking chamber.

> power" is a myth for idiots!

Another source, "John", says:

Why is food cooked in a microwave oven sometimes not cooked uniformly?

Inside the microwave oven, the microwaves bounce off the metal internal
walls and set up complex 'standing wave' patterns. As with any wave,
microwaves have peaks and troughs and the intensity of the microwaves is
greatest in the peaks and troughs and lowest at points in between.

So if some food is near one of the peaks it will absorb lots of
microwaves and get really hot, while if it is midway between peaks and
troughs it may receive hardly any microwaves and so not get very hot at
all.

http://www.bbc.co.uk/food/tv_and_radio/perfection/experimental_kitchen_microwave.shtml

So you're telling us that what cooks food in a microwave oven is the
standing waves and that it isn't because the food itself is the load for
the output of the magnetron? You'd have us believe that standing waves
which result from operating a microwave oven without such a load are
present and actually cooking food?

We can make Keith's assertion true by the addition of one
word.

"Therefore, the forward and reverse waves cannot be transferring
net energy across these points. As Ramo and Whinnery say about
the forward and reflected Poynting vectors:

If Pz+ = Pz- then Pz+ - Pz- = 0

Seems to me everything would be made clear by the addition of the
word "net". There is no net power in pure standing waves. There is
no net energy transfer in pure standing waves.

I googled diagmagnetics and found a video of a NL study where a frog (frogs are diagmagnetic, composed mostly of water) is floeating in midair when subjected to a high strength 1-10T static magnetic field. They also did the same thing with a grasshopper. It is quite interesting. What happens is that, at the molecular level, the electrons in the atoms align in such a way as to produce an opposite magnetic filed to the one they are subjected to and the magnetic force actually equals the gravitational force. Very interesting. However, electrons are not stripped off the diagmagnetic field at all and there is really nothing unusal about magnetic forces being equal to gravitational fields. Having said that, the videos on magnetic lebitation are very interesting to watch.

If you have "Fields and Waves ..." by Ramo and Whinnery,
take a look at the equation for standing wave voltage
and current on page 285 of the 2nd edition.

Ex = E*e^j(wt-Bz) + E'*e^j(wt+Bz)

Roy, that is NOT the equation for an envelope.

> the term "standing wave".

Walt is right.
Let's look at an arbitrary example of forward and reflected
voltage and current instantaneous phasors at one point on a
particular line.

Vfor = 100v at 45 degrees, Ifor = 2 amps at 45 degrees

The forward voltage and forward current are in phase.

Vref = 100v at -45 degrees, Iref = 2 amps at 135 degrees

The reflected voltage and reflected current are 180 degrees
out of phase.

Now calculate the total voltage and total current.

Total voltage = 2*100cos(45) = 141.4v at 0 deg

Total current = 2*2sin(45) = 2.83a at 90 deg

For a pure standing wave, the instantaneous voltage is
always 90 degrees out of phase with the instantaneous
current. There are no V*I*cos(A) watts in a pure standing
wave. There are only V*I*sin(A) VARS.

However, the VARS in the standing wave require energy
which can be converted to watts by I^2*R losses.

Where in the article does it say that?
Could this be a opinion planted into somebody elses work
to give it false credability?
It has been said that certain particles ,known as free
electrons/static particles, will settle on a diamagnetic
material where as other materials will reject them.
These particles are levitated when exposed to a magnetic
field. Thus I find it important to know where what you
have stated is to be found and by whose authority since
it clearly contradicts the above.

I'm surprised that standing waves seem so hard for people to understand. They're simply a spatial pattern formed by the interference between forward and reflected waves or, if you prefer, from the solution to a general transmission line problem with boundary values applied. I'd hope that even a brief look at a text would make it clear what standing waves are, and what they are not.

Electrostatic precipitation and magnetic deflection are familiar phenomena. Beyond interference and beam deflection, they have little to do with signal radiation and propagation. Radiation simply happens when a certain RF current flows along the surface of an isolated conductor and the resulting fields get too far away to be recalled by the source.

Best regards, Richard Harrison, KB5WZI

Actually, a bit more than that, even ...

Water molecules are slightly magnetic, they are spinning like hell on
those "humps of the standing wave"--friction cooking, you will excuse my
"artistic authors' license" ... or not, in ALL of this ... ;-)

However, the standing wave is much more appreciated, by me--at this
point, thanks to Cecil. And, my attention is always drawn towards
"little oddities" which can serve as diversion. And, the standing wave
IS cooking the turkey--in my humble opinion ... you could say, "I
believe in standing waves."

But then, tomorrow night, I'll be up very late with cookies and milk.
Yanno, I've never seen 'em--yet? ;-)

Regards,
JS

Roy Lewallen, W7EL wrote:
"As any text can tell you, the value of Z (ratio of V to I) varies along a line which has a reflected waves (i.e., has a standing wave)."

Not exactly, maybe the apparent Z. Uniform line is assumed and it has a Zo determined only by line structure. Zo is identical for a signal traveling in either direction. However, a directional coupler must be used to measure voltage and current traveling in one direction while ignoring voltage and current traveling in the opposite direction. A Bird wattmeter uses a directional coupler.

Voltage to current ratio on a line with reflections and standing waves is of little practical value except for determinimg whether the capacity of the line is exceeded or nearly so.

I would argue that a microwave oven uses the real power delivered to its contents and not the standing wave as an article attached to another poster`s comments stated.

Cecil, W5DXP wrote:
However the VARS in the standing wave require energy which can be converted to watts---."

VARS is an acronym for Volt Amps Reactive.
Apparent power can include real power and VARS. I would think that VARS all have volts and amps in quadrature (at 90 degrees). If so, power is VI cos theta. WI cos 90 degrees = VI (0)= 0, thus the power in VARS is 0.

Merry Christmas one and all!

I stand by my statement that Z (the ratio of V to I) varies along a line which has reflected waves.

> Voltage to current ratio on a line with reflections and standing waves

> of the line is exceeded or nearly so.

It's of essential use in the design of stub matching, impedance transformation, and a host of other transmission line applications. A Smith chart is a tool which shows this impedance, so the impedance (voltage to current ratio) is of practical value in any application for which the Smith chart is used.

Roy Lewallen, W7EL wrote:
"Certainly, the total V and I are in quadrature if the line is terminated by an open, short, or purely reactive load. But not in any other case."

Something else is at work. The reflection reverses direction of the wave producing a 180-degree phase shift in either voltage or current, but not both, if there is a reflection. Because the waves are traveling at the sane speed in approaching each other, they produce a phase reversal in a distance of only 90-degrees instead of 180-degrees. This places the waves in quadrature to stay. Terman shows the vector diagrams of incident and reflected waves combined to produce a voltage distribution on an almost lossless transmission line (Zo=R) for an open circuit case and for a resistive load case where the load is >> Zo in Fig. 4-3 on page 91 of his 1955 opus. Indeed, the angle between the incident and reflected voltages is 90-degrees in either case.

In Fig. 4-4 on page 92, Terman shows voltage and current distributions produced on low-loss transmission lines by different load impedances and in every case volts and amps are in quadrature.

Best regards, Richard Harrison, KB5WZI

No. Walter is exactly right, and don`t drag any distortionless line into the discussion. That is a device for audio circuits. For RF, you only need a low-loss (Zo = R) transmission line.

Cecil, W5DXP wrote:
"Therefore, A standing wave is not an EM wave - it is something else, by definition."

Cecil hit the nail on its head. A standing wave is an interference display of two waves of the same frequency traveling in opposite directions.

Please look carefully at those diagrams. The horizontal axis is the distance along the line. The diagrams are showing the relationship between voltage and current envelopes as a function of position. The graphs aren't showing the time phase of V and I, which is the matter under discussion.

> In Fig. 4-4 on page 92, Terman shows voltage and current distributions
> produced on low-loss transmission lines by different load impedances and
> in every case volts and amps are in quadrature.

I don't have that diagram in my 1947 Third Edition, but I'm sure that if you'll study the diagram and accompanying text you'll find that it's also a graph of peak amplitude vs position, not V or I as a function of time.

Let me pose a very simple problem. Suppose you have a quarter wavelength of 50 ohm transmission line terminated in 25 ohms and driven with a 100 volt RMS sine wave source. Consider the phase of the voltage source to be the reference of zero phase angle.

1. What is the current at the line input? [Answer: 1 ampere, at 0 degree phase]
2. What is the ratio of V to I at the line input? [Answer: 100 at an angle of zero divided by 1 at an angle of zero = 100 + j0 ohms]
3. How do you resolve this with the graphs in Terman and your explanation of the voltage and current being in quadrature everywhere along the line?

Feel free to repeat this with any other line length. I'll wait very patiently for the length which produces V and I in quadrature at the input. A very interesting result of that would be that no power would be consumed from the source, so if any reaches the load then we've created power.

I'd be glad to post the equation relating Z (the ratio of V to I) at the line input or any point along the line to the load and characteristic impedances. But I'm afraid it would be wasted effort, since there's a great reluctance here to actually work an equation or understand its meaning. But good and accurate graphs of what Richard has claimed the Terman graphs show (but don't) can be found in the _ARRL Antenna Book_. In the 20th and 21st Editions, the graphs are Fig. 12 on p. 24-9. In other editions, they're probably also Fig. 12 in the Transmission Lines chapter. In the graphs, the angle between the I and E vectors is the relative phase angle between the two, and also the angle of the impedance of the point where the vectors are shown.

On The voltage is
> indeed real, as i have said. you can measure the 'standing' wave voltage,
> that has been known for a long time... but the effects are NOT due to power
> in standing waves.-

OK, that was the least word infested post I can find...

1. A standing wave is not 'standing' in time... It phase rotates at
the same rate as the excitation frequency...
If the phase is rotating then V and I are changing - else Feynman is
rotating in his grave...
To do so requires the surface electrons at that point on the line to
oscillate back and forth <or whatever the heck surface electrons do at
rf frequency>... To excite these electrons from one energy state to
another requires power/energy/joules/whatever-you-want-to-call-it...

2. It is real because I can measure it with a volt meter and I can
extract power from it with a lamp, simultaneously..

Also: it will perforate the insulating jacket on the line if the power
level is high enough... I used to maintain a herd of 100KW RF
generators, and they would blow a hole through the side of a quarter
inch thick copper bar in an instant when the load failed <in my
youthfull ignorance, I thought it was the standing wave RATIO that
blew the line, silly me >...

Try this thought... A Tesla coil (automobile spark coil) with no load
on the output is all standing wave voltage and no current - so
according to some has no power... Touch your finger to it...
Also try: If an open ended line has 100.000 volts of DC on it, the
standing wave DC contains no power because the current is zero?

And, for whoever it was accused me of bashing someone - reread my
post, carefully.... I absolutely do not bash or flame anyone...

cheers ... denny

Roy, if you would take a "brief look at a text", you
would know NOT to try to use standing wave current phase
to measure the delay through a 75m loading coil. At any
point in time, the standing wave current phase is essentially
the same value all up and down a 1/2WL dipole including
through any loading coils. Phase does NOT equate to delay
in a standing wave environment.

It seems to me that a bit more precision in the use of language might help. So, strictly:

It is consuming power proportional to the square of the RMS current at that point on the line, and the constant of proportionality is the resistance of the line over the length of interest.

When an author writes "standing wave current", do they always mean the RMS current at a point on the line? Or do they mean the envelope of the RMS current at each point along the line? Or the envelope of the peak current at each point? Or the RMS value of the spatially distributed peak currents along the line? Or? What is THE standing wave current? No wonder there is so much dispute.

And could someone who likes to write "standing wave power" (Yuri perhaps?) please provide an unambiguous definition? It does not have to be the "right" definition, or agreed by all, just any definition which is unambiguous.

...Keith

>If the phase is rotating then V and I are changing - else Feynman is
>rotating in his grave...

true, it is 'standing' in space. it does not move along the line. your
requirement that the 'phase rotates' is another example of why a 'standing'
wave is not the same as a real wave. note the point in the standing wave
where the voltage is zero. it is always zero, there is no 'phase rotation'
at that point. now, if this was a real wave then there would be 'phase
rotation' all along the wave in both time and space.

>2. It is real because I can measure it with a volt meter and I can
>extract power from it with a lamp, simultaneously..

you can measure the superimposed voltage of the two real waves, the Vf+Vr at
each point on the line. and you can extract power from the superimposed
combination of those waves.

>Also: it will perforate the insulating jacket on the line if the power
>level is high enough... I used to maintain a herd of 100KW RF

>blew the line, silly me >...

yep, silly you. it is the superposition of the forward and reflected waves
that can create hot spots in the line. where the moving waves happen to
always be in phase you get peak voltage in the standing wave, where they
always are out of phase you get no voltage.

why do i even bother... time to start plonking more of the ones who refuse
to learn and reduce the noise level on here even more.

If one thinks about it, one will realize that an unchanging
steady-state standing wave cannot cook the turkey. Cooking
the turkey would require the standing wave to give up energy
and if it does, it is no longer a steady-state standing wave.
All of the joules/sec delivered to the load during steady-
state is from traveling-wave energy whether it be in a
microwave oven or in a transmission line.

I am not sure what lead you to think I am superposing power. The only
powers I compute are from the actual (in other words, total) voltage
and current present at one point on the line.

> take a step back and consider this:
>
> V(x,t)=Z0*I(x,t)

In my use, V(x,t) and I(x,t) are the actual voltage and current and
current at a point on the line and are only related by Z0 in very
exceptional circumstances, an example being when the line is

terminated
in Z0.

> which also must be true at every point on the line for the forward and
> reflected waves, each taken separately. so you can write equations like:
>

> (i'll leave off the (x,t) for now)

I would suggest not leaving off (x,t). I understand the short-hand but
it leads many to start thinking in terms of average or RMS. Keeping
(x,t) re-inforces the idea that the measurement is at one point and
one time.

> and by superposition you can also do:

Except that V(x,t) and I(x,t) are not, in general, related by Z0.

> Given:
> 1. you have 2 waves.

No. The two wave view is merely an alternate set of expressions
which, when summed (i.e. using superposition), provide the actual
voltage and current on the line. These alternate expressions are
obtained by algebraic maniupulation of the more fundamental
descriptive equations.

Just as in basic ciruit theory, the partial results, which are
eventually superposed to arrive at the final results, have no
particular meaning. For sure, they are not what is "really
happening".

None-the-less, this "two wave" model is extremely useful.

Are you really prepared to throw away P = VI?

In my analysis, P(x,t) = V(x,t) * I(x,t) is the equation that means
the power at any point and time can by obtained by measuring the
actual
voltage and current on the line at the point and time of interest.

Are you sure you want to throw away this ability? Are you sure you
want to claim that instantaneous power can NOT be obtained by
multiplying the instaneous measured voltage by the instanteous
measured current?

Throwing this away will invalidate much.

> 0.

It takes joules of energy for VARS to exist. Any time one
wants to give up the VARS, they can be converted to watts,
just like the energy stored in a capacitor can be converted
to watts by connecting a resistor.

The VARS stored in the standing waves in a transmission line
can be converted to watts by connecting a load equal to the
Z0 of the line. Of course, the standing waves cease to exist
in the process. One cannot have one's cake and eat it too.

yes, when the V and I are the superimposed voltage and current that you
insist are the real current and voltage on the line.

>In my analysis, P(x,t) = V(x,t) * I(x,t) is the equation that means
>the power at any point and time can by obtained by measuring the
>actual
>voltage and current on the line at the point and time of interest.

try to look at it this way. when you look at the forward and reflected
waves separately it is intuitively obvious how the power calculation shows
the flow along the line with each wave. however, when you look at standing
waves you get spots every 1/4 wave where either V(x,t) or I(x,t) is ALWAYS
zero... by V*I this means the power at that point is ALWAYS zero. since
power is just the measure of the flow of energy, and energy can neither be
created nor destroyed then in the traveling wave there can be no energy flow
past those points. where it is obvious from the individual Vf(x,t) and
Vr(x,t) or If(x,t) and Ir(x,t) that are ALWAYS related by Z0 at every point
on the line that power does flow both directions. an obvious contradiction
and if you can't see it by this point i give up.

>Are you sure you want to throw away this ability? Are you sure you

i want to throw away this falicy and replace it with the real physically
correct calculation.

>Throwing this away will invalidate much.

only in your mind.

I have said it enough times now, and hate repeating myself... so you can
live with your poor misguided assumptions and formula. i have shown the
obvious errors

Are you really saying that if I measure the instantaneous
voltage and the instantaneous current then I can NOT multiply
them together to obtain the instantaneous power?

It certainly works some of the time.

If I can not do it all the time, when can I do it?

> which has reflected waves.

What you say is true but it is important to note which
definition of "impedance", Z, that you are using. You
are using (1)(B) below, commonly referred to as the
"virtual impedance" definition because the R in the
R+jX impedance doesn't dissipate any power.

I don't think that you and Richard H. are using the same
definition of "impedance".

From the IEEE Dictionary:

"impedance -

(1)(A) The corresponding impedance function with p
replaced by jw in which w is real. Note: Definitions
(A) and (B) are equivalent.

(1)(B) The ratio of the phasor equivalent of a steady-
state sine wave voltage ... to the phasor equivalent
of a steady-state sine wave current ...

(1)(C) A physical device or combination of devices
whose impedance as defined in definition (A) or (B)
can be determined. Note: This sentence illustrates
the double use of the word impedance ... Definition
(C) is a second use of "impedance" and is independent
of definitions (A) and (B).

you can do it when it makes physical sense. it does not make sense in
standing waves for all the obvious reasons that i have pointed out. it does
make sense in the individual traveling waves. just accept what your little
swr meter tells you, it shows the forward power and reflected power, that is
all you need and the only powers that make sense.

But in the example there was a transmission line
on which the actual instantaneous voltage and
current can be measured.

And P = V * I seems rather fundamental, so V or
I is always 0, then P must always be 0.

Jumping to disussing waves does not alter this.

Seems you two are arguing about two different things.

If Z0 is purely resistive: Pure standing waves are *ALWAYS*
in quadrature, i.e. the sine of the angle between V and
I is always 1.0. Pure traveling waves are are *ALWAYS* in
phase or 180 degrees out of phase, i.e. the cosine of the
angle between V and I is always 1.0.

In a mixed environment of standing waves and traveling
waves, the angle between V and I can assume any value.

The standing wave voltage is *ALWAYS* in quadrature with
the standing wave current at all points and at all times.
If the total voltage is not in quadrature with the total
current, there is a traveling wave in the mixture.

> 1. A standing wave is not 'standing' in time... It phase rotates at
> the same rate as the excitation frequency...

Yes, but that rotation is occurring at a fixed point on
the wire. The standing wave is not moving - it is just
rotating in a fixed place on the wire. Standing waves
do not flow. They are basically an illusion created by
the superposition of two traveling waves.

> 2. It is real because I can measure it with a volt meter and I can
> extract power from it with a lamp, simultaneously..

You cannot extract steady-state power from standing waves.
You can only extract steady-state power from traveling waves.

However, you can extract transient-state power from standing
waves. That's what happens at key-up - the energy in the
standing wave is radiated after the source is disconnected.

> Try this thought... A Tesla coil (automobile spark coil) with no load
> on the output is all standing wave voltage and no current - so
> according to some has no power... Touch your finger to it...

When you touch your finger to it, it is no longer steady-state.
Standing waves can and do give up their energy as joules/sec
power during transient states. But they change during that
process.

With an open circuited line, I agree that there is no
net energy transfer at any point on the line. At most
points on the line, there is energy sloshing back and
forth, but netting to zero.

My statement about those 90 degree points where the
voltage or current is always 0 is much stronger: NO
energy transfer.

This follows inexorably from P(x,t) = V(x,t) * I(x,t).

If you disagree with the general applicability of this
equation, please indicate when it can and can not be
applied.

Confusion reigns because of steady-state short cuts.

The power density (Poynting vector) of any EM wave
is ExH. EM waves cannot exist without a power density.

For pure standing waves, ExH = 0. Therefore, a pure
standing wave is technically NOT an EM wave. It
doesn't move and contains no power. In many ways,
it is an illusion.

A standing wave is a math model created in the human
mind as a useful shortcut. Shortcuts do NOT dictate
reality. Reality is supposed to do the dictating.

Standing waves are the results of the superposition
of two traveling waves. Any power extracted comes
from the component traveling waves, not from the
standing waves. For pure standing waves:

ExH = V*I*cos(A) = 0 watts (per unit area)

How can such a signal be used to measure the delay through
a mobile loading coil?

> why do i even bother... time to start plonking more of the ones who refuse

What you have to do is overcome their programming -
that math models dictate reality, not vice versa.
Just keep dripping on that stone - someday it will
wear away.

They are the real current and voltage. I can measure them
with voltmeters and ammeters.

Directional wattmeters measure the real current and
voltage and perform some arithmetic on these measured
values to display "forward power" and "reflected power".

"Forward and reflected power" are derived from the
real voltage and current.

Absolutely. And many readers resolve the contradiction in the
wrong direction.

And then are willing to throw away P = VI.

Actually, "multiply" is ambiguous. You need to take
the *dot product* of the voltage and current to
obtain power.

Cecil,

Do you simply make this stuff up in some arbitrary fashion, or is there
a method to your madness?

With such profound statements as, "a pure standing wave is technically
NOT an EM wave", it you might either offer some sort of reference or
start planning your trip to Stockholm.

Make that *NET* power and you will be correct. There is
zero *NET* power transfer in pure standing waves.

Since Pfor = Pref, then Pfor - Pref = 0

Can you kindly articulate the rules you use to know
when it is appropriate to use P = V * I?

At a minimum, the rules should cover DC circuits,
AC circuits, and transmission lines with various
excitations and terminations. Be sure that the
rules cover 60 Hz circuits and transmission lines
since this is a common application of P = V * I.

> it does not make sense in
> standing waves for all the obvious reasons that i have pointed out. it does
> make sense in the individual traveling waves. just accept what your little
> swr meter tells you, it shows the forward power and reflected power, that is
> all you need and the only powers that make sense.

And for a challenging use case, please consider two
circuits connected together. The circuits are in black
boxes so you do not know their details, but the voltage
on the connection between the circuits is measured as
10 V RMS at 4 MHz. The current is measured as 0.

How much energy is being transferred between the
circuits?

1) P = VI, so 0.
2) P = VI some of the time, so there is insufficient
detail to answer the question.

Do you choose 1), 2) or perhaps some third answer?

...Keith

PS. The connection between the circuits is very small
so that it is possible that it is part of a
transmission line that continues into each box,
but you can not be sure.

Since the discussion concerns real numbers and not
vectors, "multiply" is exactly correct.

But you haven't answered the hard part of the question.
When does P(x,t) not equal V(x,t) * I(x,t)?

I am having great difficulty matching the words you
wrote with the request for an unambiguous definition
of "standing wave power".

Are you saying the concept is meaningless?
Or do you think you provided a definition?

I really wanted a definition from someone
who thought the "standing wave power" had
meaning.

Oooppps. Make that "so *if* V or I is always 0".

And if I had meant *NET* I would have written "net".

> Since Pfor = Pref, then Pfor - Pref = 0

Isn't that superposition of power? Something that
most agree is not a legal operation.

In any case, for sure it is 'average' power.

All my examples are using instantaneous power.
If the instantaneous power is always 0, the
average power can not be different.

What happens on a line that is terminated in a real
impedance that is not equal to Z0?

There are aspects of both travelling waves and
standing waves present on the line.

Is it appropriate to use P = V * I?

3877. Collins' Curtain Array

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-24 16:36:52 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <ZZ-dnaqZwMi_ffLanZ2dnUVZ_ternZ2d@bright.net>
Source record: 30943

Dear Antenna Group: Here is an antenna question. December 24, 2007

On the cover of the Winter 2007 QCWA Journal one may see three pictures of antennas used by Collins Radio. Two of the pictures feature a circular array of six curtain antennas. In other words, the array is expected to effect six beams - one every 60 degrees.

The curtain part of the array is straight forward. The six antennas that are in front of each curtain are new to me. It is my hope that an explanation will be forthcoming about how the front antennas "work."

Curtain description: Six, triangular, lattice towers of uniform cross section are placed equally on the circumference of a circle and guyed in four places. At least 52 (equally spaced in a vertical plane) horizontal wires are stretched between adjacent towers and the horizontal wires appear to be insulated from the towers at their ends. No noticeable sag is seen. A crude estimate suggests the towers are something like 80 to 100 feet high.

Front antennas: 17 horizontal doublets, all of essentially the same length, and all in a vertical plane that is parallel to the associated curtain emanate from a tubular mast placed in front of each curtain. [It is well known to place fat, horizontal dipoles in a broadside configuration in front of a curtain consisting of horizontal wires. At least part of the Collins' array does not look like anything I have seen before.] What I see has mirror symmetry with respect to a doublet that is in the middle of the mast. I assume that the antenna is fed with a balanced transmission line connected to the middle doublet. Above and below the middle doublet is seen exactly the same collection of doublets fed with a balanced transmission line..

Starting with the middle doublet and proceeding upward a distance that I call 3X, one encounters a collection of seven, equally spaced doublets (spaced X apart). The bottom of the group of seven is seen to be fed with a balanced transmission line coming from the middle doublet. A balanced transmission line is seen emanating from the top doublet of the group of seven for a distance 3X to an isolated doublet at the top of the mast.

If one were to ignore the groups of seven (one above the middle doublet and one below the middle doublet) one would have an antenna of three doublets in broadside with the likelihood of 1:2:1 factors so as to minimize lobes. The groups of seven could comprise two "elements" in broadside. Here is one additional fact about each group of seven: while the top and bottom doublet (of each group of seven) clearly have an attached balanced transmission line (one comes from the middle doublet and the other goes to a distal, solo doublet), the group of seven appear to be connected by a "butterfly" of what may be mesh (because one can see through the butterfly).

The butterfly is simple, but not easy to describe. It is two isosceles triangles with their bases vertical and outward from the mast, and with the apex of each triangle appearing to touch the mast at the middle doublet of the group of seven. I estimate the height (base to apex) of each half to be about X. I assume that the mesh of the butterfly is connected to each of the doublets of the group of seven.

So, who might be able to explain this?

> Best regards, Richard Harrison, KB5WZI

Great. At last we have somebody familier with this particular
phenomina
who can specifically describe why such a phenomina has NOTHING to
do with RADIATION. Richard please share with us all your deep
knoweledge
on the subject, possibly starting with the reason why diamagnetic
materials are the material of choice for radiators and if possible
references of such in a book of the modern era.. You might also
want to diverge into what makes up what is called "skin depth"
and if it consists of the same when paramagnetic are used as
radiators.
You might also comment on why the chemeical makeup of such a skin
appeares to have a constituent of 'HO' compared to the normal paired
combination of 'H20' .Could you also comment on what creats the
vibrational attributes of a radiator and how it propagates
communication means thousands of miles by deflection from
shells around the earth and in other cases pierce these same shells.
In defience of gravity no less.
To say with such confidence that electrical precipitation and
magnetic deflection has NOTHING to do with radiation implies the
suggestion that you are equal to the masters of the past and
just waiting for the chance to add to science in the new millinium.
So Richard, here is your chance to expouse on radiation together with
quoting from different books in science in a point by point fashion
to supply credability to the discussion.
Side note, I will accept any chapter from Terman, Feynman, Einstein,
Planck e.t.c.if they specifically address the points raised above
as long as what they wrote is not altered to what you think they meant
as you have done in the past.

First, start with the difference between diamagnetic and paramagnetic
materials and why one is more favorable for antennas than the other.
It is very simple but it does force one to get involved with the
facts regarding radiation especially with respect to free electrons
as opposed to bonded electrons because there is a big difference here
that appears to be overlooked
Regards
Art

Little SWR meter shows forward AND reflected power in one direction, and
reflected power only in reverse direction. Why is the Bird wattmeter
calibrated in Watts, measuring power (forward and reverse) and has chart to
calculate SWR, when there are no standing waves and no power in them?
Laying waves or sitting waves???

Seems to me that the PROBLEM is that some consider standing wave to be some
imaginary, stopped, frozen wave, no good, while some of us consider standing
wave to be the result of superposition of forward and reverse waves, that
can be (their components) measured, current heats when flowing through
resistance, voltage "burns" when poor dielectric.
Like there is standing wave current, but no standing wave, huh????
Or are we forgetting that we are dealing with electromagnetic waves?
Can someone sort out the terminology and definitions?

it is always appropriate to use P=V*I on the forward and reflected traveling
waves. it is never appropriate to use it on the standing wave voltage and
current. period... plonk.

Contributing to this news group always carries the risk of making errors and this was a DUZZY! "Power = V^2 / Zo + I^2 * Zo" IS VERY WRONG AND SHOULD NOT BE USED AS DESCRIBED. Thanks to several folks for pointing this out.

I was writing to describe a concept, a concept that was obviously wrong upon closer examination.

last time, real simple. there ARE standing current waves. there ARE
standing voltage waves. There ARE NOT standing power waves.

Why indeed? The decision of Bird Electronic to build
an instrument that measured actual line voltage and
current and then compute forward or reverse voltage
but display the result in watts has lead to enormous
confusion about the nature of forward and reverse
waves.

If only they had decided to display forward or
reverse volts, life would be much better. People
would not have internalized "forward and reverse
power" to such a degree.

On the other hand, it would have then required
more arithmetic to compute actual power.

But they did it, and it can not be undone.

Do you have an unambiguous definition of "standing
wave power" that can be used?

...Keith

Keith Dysart wrote:
> Except that V(x,t) and I(x,t) are not, in general, related by Z0.

From "Fields and Waves ..." by Ramo & Whinnery, 2nd edition:

V(x,t) = V*e^j(wt-kx) + V'*e^j(wt+kx)

I(x,t) = [V*e^j(wt-kx) - V'*e^j(wt+kx)]/Z0

Methinks you are confusing cause and effect. The standing
wave is not the cause of the two traveling waves.

> In my analysis, P(x,t) = V(x,t) * I(x,t) is the equation that means
> the power at any point and time can by obtained by measuring the

Make that the *NET* power and you will have it nailed.

> Are you sure you want to throw away this ability? Are you sure you
> want to claim that instantaneous power can NOT be obtained by
> multiplying the instaneous measured voltage by the instanteous
> measured current?

When the instantaneous voltage is the sum of two more elementary
voltages (same for current) then you are reporting the *NET*
results, not the underlying component results. The *NET* results
do not dictate reality.

> the flow along the line with each wave.

This is a very old equation:

Pnet = PLoad = Pfor - Pref = Vfor*Ifor - Vref*Iref

For a pure standing wave it reduces to:

Pnet = Pfor - Pref = 0 or |Pfor| = |Pref|

There is zero net power transfered in a standing wave
so Vtot*Itot*cos(A) = ZERO *at every point* along a
lossless line containing pure standing waves, not just
at the Vtot=0 and Itot=0 points, but *everywhere*.

> forth, but netting to zero.

It is not "sloshing" back and forth unless you consider
the speed of light to be "sloshing". That's EM photonic
energy. If it's not traveling at the speed of light, it
doesn't exist. I would describe the movement of EM wave
energy as "racing" back and forth.

> My statement about those 90 degree points where the
> voltage or current is always 0 is much stronger: NO
> energy transfer.

No *NET* energy transfer because the energy being transfered
in either direction is equal to the other direction. This
would be true of incoherent EM waves and even applies to
any and every type of wave energy.

> This follows inexorably from P(x,t) = V(x,t) * I(x,t).

Yes, it certainly does for *NET* power.
Pnet = Pfor - Pref = 0 for ideal standing waves.

> If you disagree with the general applicability of this
> equation, please indicate when it can and can not be
> applied.

It can be correctly applied when the person doing the
applying understands what it really means in reality.

I suggest you take a look at HP's s-parameter AP 95-1.
If you square the normalized s-parameter voltage equations,
you get power directly. The s-parameter equations are
designed that way.

b1 = s11*a1 + s12*a2 standard s-parameter voltage equation

a1^2 = Forward Power incident upon the impedance discontinuity

b1^2 = Reflected Power = (s11*a1 + s12*a2)^2
Power reflected from the impedance discontinuity

When a1^2 - b1^2 = 0

what do you think is the physical meaning of Reflected
Power being equal to:

Pref = (s11*a1)^2 + 2(s11*a1)(s12*a2) + (s12*a2)^2 ???

Do you recognize the irradiance equation from optical
engineering?

Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(A)

Good Grief, Gene, I don't have time to teach you
quantum electrodynamics. Go read a book that tells
you about the nature of photons. It is also the
cornerstone of relativity.

They are the *NET* current and voltage. You can separate
them into their elementary components with directional
couplers.

> "Forward and reflected power" are derived from the
> real voltage and current.

From the *NET* voltage and current by someone who understands
the nature of forward and reflected EM waves.

> start planning your trip to Stockholm.

Gene, here is a true/false quiz for you. If you have a
reference that disagrees with the obvious answers, please
quote it.

1. Is EM wave energy photonic in nature? ________

2. Do photons move at the speed of light in a medium? ______

3. Do standing waves move at the speed of light? _______

If the answers are yes, yes, and no, then standing waves
have been eliminated from the set of EM waves.

>
> How much energy is being transferred between the
> circuits?

Inside each black box is a 50 ohm signal generator equipped with a circulator and a 50 ohm load resistor. The signal generators are outputting identical 10 V RMS phase-locked signals.

Signal generator #1 "sees" the 50 ohm resistor in signal generator #2 as it's load and supplies 200 milliamp, thus heating up the load resistor.

Signal generator #2 "sees" the 50 ohm resistor in signal generator #1 as it's load and supplies 200 milliamp, thus heating up the load resistor.

The net voltage is measured as 10 V RMS at 4 MHz.
The net current is measured as 0.

How much energy is being transferred between the circuits?

Install a one wavelength 50 ohm lossless transmission line between the two signal generators. Nothing changes but the standing waves become very visible and measurable.

That is nice reading. One of the three cavaliers Richard,Richard
and Richard is going to show as all how radiation really works
and what has nothing to do with it. You never know but they may
refer to that article as back up for levitation cannot possibly
be created by a electro magnetic radiator made of a
diamagnetic material because frogs cannot communicate.
Food for thought.
Einstein,Feynman, Plank and others who revealed
much about the universe all won the Nobel prize. Yet Terman
who is revered in such matters was passed over and did not
win anything other than that which comes with writing books!
When you come to think of it he doesn't rise to the level
of Gore which itself is not a high standard

Keith Dysart wrote:
> When does P(x,t) not equal V(x,t) * I(x,t)?

Any time the angle between V(x,t) and I(x,t) is
not 0 or 180 degrees. The correct equation is:

P(x,t) = V(x,t) * I(x,t) * cos(A)

If you write the above equation as:

P(x,t) = V(x,t) * I(x,t)

then you have implied the *dot product* of those
terms. The *cross product* will give you the wrong
answer. The dot product and cross product are both
ways of multiplying so to be technically correct,
you must specify which method of multiplying that
you are talking about.

When is my bank account zero? When I have drawn out
all the money I deposited. Power is a scalar like
money. If you put in 10 watts and take out 10 watts,
the balance is zero.

If you try to put 10 watts into a load and the load
rejects it, that energy flows in the opposite direction.

P(x,t) = V*I*cos(A) = Pfor - Pref

If Pfor = 10 watts and Pref = 10 watts then
P(x,t), i.e. the *NET POWER* equals zero.

Hi, Yuri,
Cecil and Dave aren't taking resistance into account when they
talk about waves. In other words, they're not writing about real
transmission lines, coils, and such. The only lines they care about are
the ones in their minds: the simple ones where the attenuation constants
are always zero, and current and voltage are always either in phase, or
90 degrees out of phase, and there is never any dielectric breakdown, no
matter the voltage. You can only feel sorry for guys like that.

using any decent coax of a reasonable length and typical amateur power
levels the assumptions we have stated are very close to the actual results.

if you want to examine lossy lines in detail then go ahead, the formulas get much messier and without proper formula rendering on a newsgroup they are almost impossible to discuss... and for the concepts that have been proposed the ideal lossless line case is perfectly acceptable.

And from an earlier post, Keith wrote

"Are you really saying that if I measure the instantaneous
voltage and the instantaneous current then I can NOT multiply
them together to obtain the instantaneous power?

It certainly works some of the time.

If I can not do it all the time, when can I do it?"

You give a good example Keith. It would be correct for measurement at the load and at every point 1/2 wavelength back to the source from the load, because the standing wave has the same measurements at these points. At the 1/4 wavelength point back from the load and every successive 1/2 wave point back to the source, the equation would also be correct as demonstrated in Roy's example earlier today.

Excepting for these points, we would also be measuring a reactive component that could be described as the charging and discharging of the capacity or inductive component of the transmission line. (Imagine that we are measuring the mismatched load through a 1/8 wave length long transmission line, using an Autek RX VECTOR ANALYST instrument) The inclusion of this reactive component would invalidate the power reading if we were assuming that the measured power was all going to the load.

I would visualize the situation by saying that at the points mentioned, the peaks of the traveling waves match as they pass each other going in opposite directions each cycle. At all other points, the matching is peak of one plus part of the second, so that the resulting measurement can always be described as containing a quadrature (or reactive) component.

> Are you saying the concept is meaningless?
> Or do you think you provided a definition?

"Standing wave power" is an oxymoron. There is simply zero power in standing waves. The dot product of the net voltage and net current in an ideal standing wave is always ZERO.

Power (watts) is the measure of energy (joules) passing a measuring point in one second. One can measure the forward power. One can measure the reflected power. One cannot measure any standing wave power because it is always equal to (Pfor - Pref) which for ideal standing waves is *always* zero.

If the net energy flow is zero, as it is in ideal standing waves, the power is zero, by definition, because zero net joules are flowing. And, sure enough, the standing wave voltages phasors are *always* 90 degrees away from the standing wave current phasors and they are not moving left or right. They are rotating around a fixed spacial point on the wire.

Standing waves are a very sophisticated illusion.

your motive is to obscure)?

>> Since Pfor = Pref, then Pfor - Pref = 0
>
> Isn't that superposition of power? Something that
> most agree is not a legal operation.

No, that is simply an accepted engineering convention
that has been around since long before you and I
were born.

PLoad = (+Pfor) - (+Pref)

The negative sign doesn't mean negative power. It is
simply a directional convention for the Poynting vector
that indicates the direction of energy flow.

A negative sign is often used to denote direction (or
a 180 degree shift).

Dollars going into your bank account and coming out of
your bank account are all the same scalar dollars. The
direction in which they are flowing is denoted by a
plus or minus sign.

Hi Keith,
When you take the real part of P = VI*, where
I* is the complex conjugate of the current, you're computing
the power in the transmission line. However, the imaginary
part of VI* doesn't disappear, and you should be aware of
its existence if you're going to put a lot of energy into
said line (unless it's a perfect Cecil//Dave line with no
attenuation etc). Yuri is probably arguing from experience
with real lines. Cecil/Dave are arguing from an idealized,
but flawed understanding of the subject. All of them should
go back to school and study the whole elephant, so they won't
keep making the same mistakes the three blind men made.

Richard, a lossless line is a special case of a distortionless line (ie all lossless lines are distortionless lines, but not vice versa).

Specifying a distortionless line is less limiting than restriction to only lossless lines.

You are actually proposing a greater restriction than I, and it isn't necessary.

It does not fail. Present any example of a transmission line terminated with a load. Choose any line and load impedance and any transmission line length. I'll tell you the V and I at any point on the line, calculate the instantaneous power from V(t) * I(t) at that point, and from that the average power. Then I'll show that this average power equals the power in the load and the power delivered by the source. As an added bonus, I can tell you the impedance (ratio of V/I) at any point along the line. I'll provide both equations that always work and numerical results.

Then you can show where I've made an error and why my calculations are invalid.

Can I be any more fair than that?

Roy Lewallen, W7EL

Hopefully, you realize that P = VI only works for DC.
AC and RF, with their associated phase angles, are much
more complicated than P = VI. As a matter of fact, if
you use P = VI for standing waves, you are infinitely
wrong. There is no power in standing waves no matter
what the voltage and current magnitudes.

Let' start with the easiest parts to debunk first:

>> The electron itself is a photon that cannot propagate because of its own
>> self gravity.

No it is not. A photon by definition has no rest mass. An electron as rest mass about 1/2000 that of a proton.

BTW, is a proton also a photon? ;-)

>>The enclosed self energy is such that the photon cannot propagate. "Stuck
>>light" in fact.

Yeah, stuck light. Right.

>> This photon is waving outside the stuck place so its influence can be
>> felt over an infinite distance. In fact, using the group x phase velocity
>> = constant we have that for electrons the group velocity is 0 and the
>> constant is c so the phase velocity is infinite.

Good logical leap using semantics instead of science.

>> so for some interactions like entanglement (a consequence of Fermi
>> (electrons come in pairs - up and down)) then the change of an electron
>> up to down that is tangled with it pair 10 light years away will be felt
>> instantaneously and the other member of the pair will change from down to
>> up with no loss of amplitude.

Now this is the best one yet. This tells us that we can have information flow at several times the speed of light, just generate your zero's and one's with up/down elctrion pairs 10 light years way, for instantaneous communication.

>>
>> This might be of interest too ...

It sure would...to IBM or anyone else trying to make faster than light computers. I guess you get the answer to the problem before you ask the question ;-)

The errors and misconceptions are so great, where does one start?

Good grief, Roy. The net voltage is 100v. The net current
is 1 amp. The load is infinite. P does NOT equal 100 watts.
P equals zero. P does not equal V * I. P = V*I*cos(A) where
A = 90 degrees.

What the hell is wrong with you people?

Cecil,

I recall from some previous messages that you may have read Feynmann's QED. Why don't you add some Feynmann diagrams into this discussion and edumacate us all? (I can answer that one: you wouldn't know what to do with a Feynmann diagram if it bit you on the behind.)

More to the point. If you would stop the silly business about "net" everything you might begin to understand that standing waves have effects that move at the speed of light just in the same manner that traveling waves do. Do you really believe that the fields from the standing waves don't propagate?

Perhaps you should review the difference between static and stationary. The standing wave is stationary. It is not static.

Cecil,

Too easy.

1. Yes, but who cares? If you want to go beyond ordinary classical models, then most of your standard formalism about transmission lines would need a bit of work. Classical works pretty well for HF.

2. Yes.

3. Yes.

Do I win the prize?

> . . .

Well, let's look at that problem. Make the line 1/8 wavelength long instead of 1/4 wavelength. The ratio of V to I at the source can be calculated directly with a single formula or by separately calculating the forward and reverse traveling voltage and current waves and summing them. The result, for my 50 ohm transmission line terminated with 25 ohms, is 40 + j30 ohms. V at the input is fixed by the source at 100 volts RMS. I = V / Z = 1.6 - j1.2 amps = 2.0 amps magnitude with a phase angle of -36.87 degrees.

Now I'll translate V and I into time domain quantities. (I could have calculated I directly in the time domain, but this was simpler.)

Using w for omega, the rotational frequency,

If V(t) = 141.4*sin(wt) [100 volts RMS at zero degrees] then
I(t) = 2.828*sin(wt-36.87 deg.) [2 amps RMS at -36.87 degrees]

Multiplying V * I we get:

V(t) * I(t) = 400 * sin(wt) * sin(wt - 36.87 deg.)

By means of a trig identity, this can be converted to:

= 200 * [cos(36.87 deg) - cos(2wt - 36.87 deg.)]

cos(36.87 deg) = 0.80, so

V(t) * I(t) = 160 - 200 * cos(2wt - 36.87 deg.)

This is a waveform I described in my previous posting. The cosine term is a sinusoidal waveform at twice the frequency of V and I. The 160 is a constant ("DC") term which offsets this waveform. The fact that the waveform is offset means that the power is positive for a larger part of each cycle than it is negative, so during each cycle, more energy is moved in one direction than the other. In fact, the offset value of 160 is, as I also explained earlier, the average power. It should be apparent that the average of the first term, 160, is 160 and that the average of the second term, the cosine term, is zero.

Let's see how this all squares with the impedance I calculated earlier.

Average power is Irms^2 * R. The R at the line input is 40 ohms and the magnitude of I is 2.0 amps RMS, so the power from the source and entering the line is 2^2 * 40 = 160 watts. Whaddaya know. Let's try Vrms^2 / R. In this case, R is the shunt R. The line input impedance of 40 + j30 ohms can be represented by the parallel combination of 62.50 ohms resistive and a reactance of 83.33 ohms. The 62.50 ohms is what we use for the R in the V^2 / R calculation. Vrms^2 / R = 100^2 / 62.50 = 160 watts.

We can also calculate the power in the load from its voltage and current and, with the assumption of a lossless line I've been using, it will also equal 160 watts.

P = V(t) * I(t) always works. You don't need power factor or reactive power "corrections", or to have a purely resistive impedance.

This is really awfully basic stuff. Some of the posters here would come away with a lot more useful knowledge by spending their time reading a basic electric circuit text rather than making uninformed arguments.

Yes, the standing wave fields do not propagate so that should
be a clue that they are somewhat unrelated to reality. That the
standing wave fields do not propagate can be seen in the phase
of the standing wave current as reported by EZNEC - it doesn't
change by more than a negligible amount over the entire length
of a 1/2WL dipole just as Kraus reported:

http://www.w5dxp.com/krausdip.gif

> Perhaps you should review the difference between static and stationary.
> The standing wave is stationary. It is not static.

I don't recall uttering the word "static". Perhaps you would like
to quote me and prove me wrong. If you cannot, would you like
to admit that you are just blowing smoke?

Of course not. Please explain how standing waves can
move at the speed of light yet only change phase by 1/10
of one degree in 90 degrees of transmission line or antenna?
Please be technically specific and include the math.

We cannot wait to hear your answer to that one.

Whoops, that is not possible for your V & I scalar values.
Please don't tell us that you are using ASCII characters,
normally reserved for scalar values, for phasor values,
without telling anyone what you were doing. Do you think
that is ethical?

Roy, try a real simple case.

50 ohm line, 1/2 wavelength long, open circuit, lossless, sinusoidal steady state, fed with a 1v p-p voltage source.

Everyone will agree there is a standing wave on this line of course.

now, to make everyone happy... in the middle of the line calculate v(t), i(t), and p(t), these are the standing wave voltage, current, and power.

now, calculate vf(t), if(t),pf(t), vr(t), ir(t), pr(t) at that point, where the 'f' terms are the forward wave, the 'r' terms are the reflected wave.

compare and comment on the relation between pf, pr, and p.

extra credit:
repeat calculations at the far end of the line. again compare pf, pr, and p.

Thanks for the example of P = V(t) * I(t).

I think the example illustrates why the instantaneous power equation P = V * I that Keith was referencing is not appropriate at all points on the line. If I understood Keith correctly, he would have calculated 200 watts input for your example (100 volts at 2 amps).

Do it yourself, Dave. Or, better yet, ask Cecil to do it. Anyway, you
made a mistake in the question. Can you discover what it is?

Huh? I calculated 160 watts using P = V(t) * I(t). Why do you think Keith would have calculated 200 from the same equation? I have no doubt that his math skills exceed mine, and I used nothing more than complex arithmetic and high school trig.

I calculated power at the input end of the line, but I can calculate it from the same equation P = V(t) * I(t) at any point on the line, and will get exactly the same result. At what point(s) do you think it's not "appropriate" to use?

I know.

I guess you don't have to go very far to see where some of these extravagant concepts originate. You don't have to google on diamagnetics very long before you run into levitation and then videos of frogs floating in the air when subjected to 10T magnetic fields (which are true). From there it is no big deal to talk about levitating electrons from antennas and grand unification theories which have their own large numbers of google hits. Nothing need be left to the imagination; just fit the pieces of the puzzle together like Einstein did except for....oops...one small detail: Albert did not depart from a strict mathematical model in favor of science fiction. Was that Diamagnetics ot dianetics? ;-))

What is it that makes you and David so angry with somebody proposing a
theory?
Do you really think that all is known about radiation and thus you are
firmly
equipped to debunk change?

> now, to make everyone happy... in the middle of the line calculate v(t),
> i(t), and p(t), these are the standing wave voltage, current, and power.

No problem.

Let's use the voltage source as the phase reference, so it will be
(using w to represent the rotational frequency omega):

v(t) at the line input = 0.5 * sin(wt)

At the center of the line, i(t) = 0.02 * sin(wt - 90 deg.) and v(t) = 0.

p(t) = v(t) * i(t) = 0

Note that this isn't the average power (although the average power is
also zero), but the instantaneous power -- meaning that the power at
that point is zero at all times.

These aren't "standing wave" voltage, current, and power, but simply the
total voltage and current, and the power, at that point.

> now, calculate vf(t), if(t),pf(t), vr(t), ir(t), pr(t) at that point, where
> the 'f' terms are the forward wave, the 'r' terms are the reflected wave.

At the center of the line,

vf(t) = 0.5 * sin(wt - 90 deg.)
if(t) = 0.01 * sin(wt - 90 deg.)
vr(t) = -0.5 * sin(wt - 90 deg.)
ir(t) = 0.01 * sin(wt - 90 deg.)

where I've taken the positive direction of ir to be forward, the same as if.

> compare and comment on the relation between pf, pr, and p.

Calculation of P(t) is as follows:

p(t) = v(t) * i(t) = [vf(t) + vr(t)] * [if(t) + ir(t)]

= 0 * 0.02 sin(wt - 90 deg.) = 0 as calculated before.

I haven't seen a definition of pr and pf, but they're not relevant to the discussion. If you get a different result for power than zero by using whatever you take them to mean, then the concept is invalid. There is no average power leaving the source and no average power being dissipated in the load(*). So there had better be no average power anywhere in the line. There will be non-zero instantaneous power everywhere along the line except at the input, far end, and midway, but its average value will be zero, indicating the movement of energy back and forth but no net energy flow.

> extra credit:
> repeat calculations at the far end of the line. again compare pf, pr, and
> p.

Sure.

At the far end of the line,

v(t) = sin(wt - 180 deg.)
i(t) = 0

p(t) = v(t) * i(t) = 0 at all times.

vf, if, vr, and ir, are the same everywhere on the line, so see the previously calculated values. Likewise, the calculation of p(t) from the forward and reverse traveling waves is the same as before, with the same result.

I've shown that I can calculate the correct power at two points along the line by using p(t) = v(t) * i(t) as I can for any point on any line with any termination. Your question implies that the results I got (zero at all times at both points) are incorrect. What power (instantaneous and average) do you calculate for those two points?

(*) In fact, calculation of the power at the source will show that the power there is also zero at all times. The energy moving back and forth in the line at all points except the quarter wavelength nulls was put into the line during the turn-on process. After steady state has been reached, the source can be turned off (converted to a short circuit) with no change in what's happening on the line.

If you'll look back through Keith's postings you'll see that he was referring to the functions of time. It looks like he left off the explicit (t) at some places which would lead to confusion.

But I hope you realize that you can also find the average power just fine by calculating Pavg = Vrms * Irms * cos(theta) at any point along the line, where Vrms and Irms are the total voltage and current at the point, and theta is the angle between the two. This is true regardless of the SWR. Also, you can calculate power as Irms^2 * Rser or Vrms^2 / Rpar where Rser and Rpar are the series and parallel equivalent resistive parts of the impedance at any point. Like v(t) and i(t), Vrms and Irms can be found if desired by summing the forward and reflected waves to find the total value at the point of interest; superposition applies. It doesn't apply to power, so always do the summation of voltages and currents before calculating power.

One property of the P(t) = V(t) * I(t) equation is that it also applies to non-sinusoidal and even non-periodic waveforms -- it can *always* be used. And you can always find the average power by integrating it then dividing by the integration period. The average value calculation reduces to Vrms * Irms * cos(theta) for pure sine waves but not other waveforms.

Roy Lewallen, W7EL

3933. Re: Standing-Wave Current vs Traveling-Wave Current

Source record: 30800

Correction:

Roy Lewallen wrote:
> . . .
> vf, if, vr, and ir, are the same everywhere on the line, so see the
> previously calculated values. Likewise, the calculation of p(t) from the
> forward and reverse traveling waves is the same as before, with the same
> result.

This isn't true. The phase angles of these terms are different at different places along the line, so the p(t) results are different. At the load end of the line:

vf(t) = 0.5 * sin(wt - 180 deg.)
if(t) = 0.01 * sin(wt - 180 deg.)
vr(t) = 0.5 * sin(wt - 180 deg.)
ir(t) = -0.01 * sin(wt - 180 deg.)

At this point, the result for p(t) is still zero at all times because of zero ir + if rather than vr + vf as at the center of the line. At other points along the line, as I mentioned in the original posting, p(t) will end up being non-zero -- it'll be a sinusoidal function with rotational frequency 2wt. But it will have an average value of zero, indicating movement of energy back and forth but no net energy flow over an integral number of periods.

I apologize for the error.

May everyone have an enjoyable and peaceful holiday.

Roy Lewallen, W7EL

Good Grief, Roy, no wonder you are clueless about standing
waves. In a lossless open-circuit line, the total voltage and
current *ARE* the standing-wave voltage and current because
traveling wave current and voltage doesn't exist. Good Grief!

Electrons cannot be radiated from the surface of an antenna, diamagnetic or
otherwise. Think of it in terms of Guass's law: The E field resulting from
the charge on the antenna must always be equal to the charge on the other
side of an area integral of the projected surface over the wire.

IF a net volume of charge exits the antenna, then we have an imbalance and a
violation of Gauss's static law on the other side of the Gaussian surface.

And you are absolutely sure that your above analysis is correct and
without any
possible doubt what so ever and nothing to the contrary can possibly
be accepted
based on your perceived logic that your brain cannot be wrong with
respect
to its analytical processes?
Then how do you explain that using Gaussian logic or model that you
are quoting
is the same as Maxwells law when a time varient is added?
And to repeat my earlier question, what is it that makes you and David
so angry
at the suggestion of an alternate theory?
Art

And you are absolutely sure that your above analysis is correct and
without any
possible doubt what so ever and nothing to the contrary can possibly
be accepted
based on your perceived logic that your brain cannot be wrong with
respect
to its analytical processes?

YES INSOFAR AS I AM ABSOLUTELY CONVINCED THAT GAUSS'S STATIC LAW AS ONE OF THE MAXWELL EQUATIONS IS ABSOLUTELY CORRECT.

Then how do you explain that using Gaussian logic or model that you
are quoting
is the same as Maxwells law when a time varient is added?

OK, LET US ADD A TIME VARIANT. MAXWELL'S STATIC LAW MUST BE TRUE DURING ANY TIME INCREMENT FROM T= 0 TO T = INFINITY. THAT IS MY POINT. AS SOON AS YOU START EJECTING STATIC CHARGES FROM WHATEVER ANTENNA SURFACE YOU ARE SUGGESTING, YOUR YOUR ASSERTION DOES NOT HOLD UP TO GAUSS'S LAW. SORRY ABOUT THAT BUT THAT'S THE WAY IT IS.

And to repeat my earlier question, what is it that makes you and David
so angry
at the suggestion of an alternate theory?

YOU ARE VERY CLEVER TO SAY YOU "SUGGEST" AN ALTERNATE THEORY. THIS, AS OPPOSED TO ACTUALLY "PROPOSING" AN ALTERNATE THEORY. NOBODY IS ANGRY ART BUT WE ARE ALL WAITING FOR YOUR PROPOSAL IN THE LANGUAGE OF MATHEMATICS. ALL ELSE IS BS, NO BETTER THAN THE NIGERIAN "PROFESSOR" SCAM ARTIST'S Gij, j=0 UNIFICATION THEORY.

Sounds like a good antenna to try - except the XYL will really make herself an "ex" after seeing the array. Some of those XYLs just don't understand!

Thanks again Roy. Your last two postings have been very helpful. While I am aware of these relationships, I do not use them often and each use seems like a first time. So I try to be very careful, but still make bad errors as you saw yesterday.

I try not to be too critical of any postings, but (as Cecil warns) the standards of knowledge and explanation are very high on this news group, and misuse (even accidental) of terms or equations are noted and frequently flamed or worse. Participants need a thick skin and persistence, but a great deal can be learned here. I find it to be quite a learning experience and proving ground.

Merry Christmas!

I have shared everything that I have so there is no more to share.
The law association between Gauss and Maxwell is now a proven fact.
There is no imbalance as you have suggested. All existing antenna
computor programs confirm the validity of the association.
Feynman agrees on the validity of the association.
But if all this theory in error then why are you so bothered about it?
I have no problem with you calling it BS but why resort to defermation
because I will not change my beliefs to those that you hold?
What I am proclaiming is part and parcel of free speech, and as
can be seen with more than a thousand posts and a few personal
attacks this group has not been able to silence Cecil.
What is so important that all participants on this newsgroup
must be a clone of yourself or you will mount personal attacks?
The group has been addressed by a Doctor from MIT with respect
to the mathematics.An independant participant verified an
antenna in equilibrium as being valid using his own antenna
computor program. Jackson's book confirms the association of
Gauss with Maxwell as well so why attack me when I am following
established positions because they are different from yours ?
As for proposing a theory I have done exactly that by presenting
it to my peers who are knoweledgable in the field. On top of
that I have spent good money in a application to the Patent office
even tho you may disagree on the propriety of those acts.
Fortunately there are some on this group do not recognise
the gown of infallability that you, David and a couple of
other people wear.
I obtained review of my research from knoweledgable
people in the field as well as building the antennas before I
went for peer review so frankly what you and David think
pales in the face of those knoweledgable in physics.
It just amazes me that some people get so angry
over something that doesn't affect their lives one tiddly bit
such they wish to sully another. I really don't know what
it is that you are searching for in life or if your needs
are insatiable.

I have shared everything that I have so there is no more to share.
The law association between Gauss and Maxwell is now a proven fact.
There is no imbalance as you have suggested. All existing antenna
computor programs confirm the validity of the association.
Feynman agrees on the validity of the association.
But if all this theory in error then why are you so bothered about it?
I have no problem with you calling it BS but why resort to defermation
because I will not change my beliefs to those that you hold?
What I am proclaiming is part and parcel of free speech, and as
can be seen with more than a thousand posts and a few personal
attacks this group has not been able to silence Cecil.
What is so important that all participants on this newsgroup
must be a clone of yourself or you will mount personal attacks?
The group has been addressed by a Doctor from MIT with respect
to the mathematics.An independant participant verified an
antenna in equilibrium as being valid using his own antenna
computor program. Jackson's book confirms the association of
Gauss with Maxwell as well so why attack me when I am following
established positions because they are different from yours ?
As for proposing a theory I have done exactly that by presenting
it to my peers who are knoweledgable in the field. On top of
that I have spent good money in a application to the Patent office
even tho you may disagree on the propriety of those acts.
Fortunately there are some on this group do not recognise
the gown of infallability that you, David and a couple of
other people wear.
I obtained review of my research from knoweledgable
people in the field as well as building the antennas before I
went for peer review so frankly what you and David think
pales in the face of those knoweledgable in physics.
It just amazes me that some people get so angry
over something that doesn't affect their lives one tiddly bit
such they wish to sully another. I really don't know what
it is that you are searching for in life or if your needs
are insatiable.

OK ART, CALM DOWN. LET US KNOW WHEN YOUR PATENT GETS ACCEPTED AND PUBLISHED.
I WILL BACK OFF FROM INVOKING THOSE NASTY FUNDAMENTAL PRINCIPLES OF
ELECTROMAGNETISM. I WOULD'NT WANT TO LET PRIOR ART STAND IN YOUR WAY.

You are quite unfair to Ramo & Whnnery when you quote them
out of context. It makes them look like they do not have a
clue.

Just because you find the same string ["V(x,t)"] in their
text does not mean that they are talking about the same
thing. (It better not in this case, or you should throw
their book away.)

You, yourself, have made the point in other posts that
the current and voltage on an open circuited line are
in quadrature, so they can not be in the ratio of Z0.

Of course not. "Standing wave" is just a short hand description
of the distribution of voltage and current on the line.

so roy has correctly calculated the standing wave 'power' to be zero at two points on the line. i am sure that yuri will take great exception to this result showing there is no power in the standing wave.

but he missed the definition of pr and pf...

dave in problem statement:
> now, calculate vf(t), if(t),pf(t), vr(t), ir(t), pr(t) at that point,
> where
> the 'f' terms are the forward wave, the 'r' terms are the reflected wave.

so he conveniently skipped that step and instead writes this cop out:

roy:
>I haven't seen a definition of pr and pf, but they're not relevant to
>the discussion. If you get a different result for power than zero by
>using whatever you take them to mean, then the concept is invalid.

pr and pf are, as i stated, the power in the forward and reflected waves. There is of course power in these two waves and it is indeed 'sloshing' back and forth in the line. These are the waves that can be measured by any of the simple devices such as neon bulbs or bird watt meters that clearly show equal and opposite powers in the waves. so you can indeed have power in the traveling waves, but no power in the standing waves... which will always be the case.

i will give him this point as being correct for a lossless open (or shorted) line:

>There
>is no average power leaving the source and no average power being
>dissipated in the load(*). So there had better be no average power
>anywhere in the line.

but then he loses it again:

>There will be non-zero instantaneous power
>everywhere along the line except at the input, far end, and midway, but
>its average value will be zero,

the traveling waves will have power EVERYWHERE on the line, the special cases are are just the ones where the standing wave is most easily shown as having no power. obviously if there is power in a wave at one point on a line it is not going to stop and bypass the quarter wave points, the forward and reflected waves continue end to end and their power goes with them... it is at those 'special' points where the voltage or currents in the forward and reflected waves always cancel each other so if you measure with a simple

tool you will see the voltage or current nulls at those points. that does not mean there is no power passing those points, only that the voltage or current in the traveling waves has conveniently canceled each other out at those points.

and then he has to end up with an obvious contradiction:

> indicating the movement of energy back
>and forth but no net energy flow.

how does energy not flow if it is moving back and forth???

or FAQ depending on how you look at it... I should probably repeat this regularly on here.

This newsgroup should NOT be used as a reference source for concepts or equations regarding fields, waves, transmission lines, or other physical phenomena. Please consult published text books and peer reviewed journals for analysis of technical questions. The regular contributors in this group have a wide variety of misconceptions and erroneous views which they frequently throw in as if they were well known facts.

On the lighter side, it can be fun now and then to throw them a simple problem and watch them swarm around like a kicked hornet nest.

> current *ARE* the standing-wave voltage and current because
> traveling wave current and voltage doesn't exist. Good Grief!

Hmmm, Like Roy, I thought there was still a traveling wave in this situation. The voltage at the far end of the line must reverse polarity as time passes, so the waves must continue to travel, or so I would think.

Maybe it could be said better, but I thought Roy was trying to say that although power could not be detected at the center or ends, it was flowing as a result of the initial impetus charged into the system. I would understand that this power would be the power needed to charge the impedance and capacity of the line as it continually reversed polarity. This would be real power from energy stored (but constantly moving) on the 1/2 wavelength line so long as the system is active. We know we have power present because we find energy distributed as V and I on the time plot (viewed as a "standing wave" on the time plot).

Is this a "tongue-in-cheek" comment?

> You are quite unfair to Ramo & Whnnery when you quote them
> out of context. It makes them look like they do not have a
> clue.

It's not out of context. Those are their equations for
standing wave voltage and standing wave current. It is
net voltage and net current because each equation is
the sum of two component values.

> Just because you find the same string ["V(x,t)"]

Actually, it wasn't the same string. R&W used 'z'
instead of 'x' for the length of the wire as was
common a half-century ago when I had their textbook
for both undergraduate and graduate level courses.

> in their text does not mean that they are talking about
> the same thing. (It better not in this case, or you should
> throw their book away.)

But they *are* talking about the same thing. The first equation
above is the total (standing wave) voltage. The second equation
is the total (standing wave) current. The only term difference
between the two equations is the Z0 term. There is a sign difference
in the current equation that shifts the reflected current by 180
degrees putting the net voltage and net current in quadrature.

Methinks suggesting that Ramo & Whinnery should be thrown away
is "delusions of grandeur".

> You, yourself, have made the point in other posts that
> the current and voltage on an open circuited line are
> in quadrature, so they can not be in the ratio of Z0.

Nobody said they are "in the ratio of Z0" and that's not
what you said before either. You said they are "not related

by Z0" and they are related by Z0 just as the above equations
demonstrate. You didn't say "ratio", you said "related".

The ratio of standing wave voltage to standing wave current
above is:

```
V(x,t) V*e^j(wt-kx) + V'*e^j(wt+kx)
------ = ---------------------------------- = Z
I(x,t) [V*e^j(wt-kx) - V'*e^j(wt+kx)]/Z0
```

This is the old familiar SWR circle on the Smith Chart.
Smith Charts are normalized to Z0 = 1.0. The impedance
on the Smith Chart must be multiplied by Z0 to get the
actual impedance. Those impedances are indeed
"related to Z0". The s-parameter signals are normalized
to the square root of Z0. Vfor/Ifor = Vref/Iref = Z0.
Virtually everything about a transmission line is "related"
to Z0 including the standing wave voltage and current.

>> Methinks you are confusing cause and effect. The standing
>> wave is not the cause of the two traveling waves.
>
> Of course not. "Standing wave" is just a short hand description
> of the distribution of voltage and current on the line.

Yes, a "short hand description" that exists only in the human
mind and gets some folks into trouble - like trying to use
the illusion of moving standing wave current to "measure"
the delay through a coil. There is no standing wave current
movement through a coil or a wire. Standing wave current
doesn't move - it just stands there, oscillating in place.
EM current that doesn't move is obviously an illusion (and
a violation of the laws of physics).

Here's what Eugene Hecht said about standing waves in "Optics".

"It [the standing wave phasor] doesn't rotate at all, and
the resultant wave it represents doesn't progress through
space - it's a standing wave."

Applied to a wire or a loading coil, we can paraphrase -
standing wave current "doesn't progress through" a wire or
a loading coil - "it's a standing wave". EZNEC supports this
concept. Take a look at the current phase for a 1/2WL wire
dipole. From one end of the dipole to the other, the total
current phase varies by only a couple of degrees. Kraus agrees:

http://www.w5dxp.com/krausdip.jpg

> Sorry Cecil. The observed voltage and current on the line
> are the reality.

The net voltage and net current are real but their independent
existence apart from the underlying traveling waves is just

an illusion. They are not independent. They are the *result*
of superposition of the forward and reverse waves. They are
merely an *effect* and not the cause of anything.

There are lots of real illusions. That beautiful Texas
"sunrise" this morning was just an illusion, an effect of
the rotation of the earth.

The best confession yet :-)

Just my two centavos.
I enjoy this group because it is not policed by the Gestapo moderator and is open to variety of opinions and allows niiiice loooong threads leading to some conclusions and bringing up points that otherwise would be neglected.
It is a mirror of some personalities, uncovering their real repository of knowledge, right or wrong, testing the convictions and stubbornness on sometimes sticking to their false truths. But those with some open mind left can make their own conclusions and learn a thing or two.
What a difference to say Towertalk reflector where i.e. W8JI (the great technical imposter - as summed by K7GCO) can decimate opponent of his "gospels" while Gestapo admin will delete any opposition to his "teachings" and leave the last man standing with his fallacies still on his web site.
Too bad, because many decent posters get turned off and fade away just disgusted by it.
So, thanks to youze guyz for your contributions to the warfare here, it is the best, stimulating and a mirror of various contributors that paint the pictures of themselves with their arguments.
I have learned from my burned up Hustler coil mystery all the way to "no power in standing waves" and where all those electrons, photons and other antenna creaters go when I feed them power.

Merry Christmas and a Happy, Healthy New 2008!

Yuri, K3BU, VE3BMV etc

Power is the measure of the energy flow past a measurement
point. There is no net energy flow in pure standing waves.
Since the standing wave current phasor is always 90 degrees
different from the standing wave voltage phasor,

Power = V*I*cos(90) = 0 watts Note that V and I do not
have to be zero. There is simply no real power in a pure
standing wave. However, there are plenty of joules in
standing waves that can be converted to real power at
the expense of the standing waves after key-up.

All of the standing wave energy is contained in

Reactive Power = V*I*sin(90) in units of VARS

From the IEEE Dictionary:

"reactive power - For sinusoidal quantities in a two-wire
circuit, reactive power is the product of the voltage,
the current, and the sine of the phase angle between them."

It is common practice to divide the waves into standing waves
and traveling waves so they can be discussed separately. For
instance, if the forward voltage is 200 volts and the reflected
voltage is 100 volts, we have a mixture of standing waves and
traveling waves.

It is common practice to allocate 100 volts of the forward wave
to the standing wave in order to exactly match the reflected
voltage with the resultant *pure standing wave*.

The other 100 volts is allocated to the *pure traveling wave* that
is making its way from the source to the load. That's how my profs
at Texas A&M chose to teach the subject. It's a sort of reverse
superposition technique that makes everything crystal clear in
a system of mixed standing waves and traveling waves.

> Is this a "tongue-in-cheek" comment?

You think? :-)

Note that in a pure standing wave, the magnitudes of the forward
wave and reflected wave are identical.

There's plenty of energy in those standing waves, Yuri,
existing as "reactive power" as defined by the IEEE
Dictionary (units of VARS from power engineering).

When any energy is extracted from a standing wave and
used to heat the Hustler coil, it automatically becomes a
traveling wave with the voltage and current in phase, not
a standing wave with the voltage and current 90 degrees out
of phase. Your Hustler coil was burned up by traveling waves,
not standing waves.

Hello All:

I have sent Yuri e-mail telling him how I liked his Razor Antenna and enjoyed his writings and such. But got no reply. Maybe didn't get thru the filter?!?!?

This RRAA is a good group as I for one, watch and read, and then reread and look thru a few books. It is a healthy group. And at times real entertaining. As Yuri said it has many different views and considerations not mention in most books and such are presented.

Setting back on the side lines and watching.

Merry Christmas to all.

Jay in the Mojave

In the case of an open circuited line, the voltage traveling wave maintains the same polarity upon reflection from the end of the line. Mathematically, the voltage reflection coefficient is +1. The voltage and current traveling waves continue to travel after reflection, which results in the interference pattern known as a standing wave.

> Maybe it could be said better, but I thought Roy was trying to say that
> although power could not be detected at the center or ends, it was
> flowing as a result of the initial impetus charged into the system.

It's easy to confuse power and energy, and I've been careful to use those terms correctly. Power is the rate of energy flow, and I said nothing about power flowing. (That's Cecil's concept, and careless application of it leads to irreconcilable problems.)

> I
> would understand that this power would be the power needed to charge the
> impedance and capacity of the line as it continually reversed polarity.

Capacitance is charged by charge, which is the integral of current, so you can if you want track the charging and discharging of the line's capacitance by integrating the current. Impedance is the ratio of V to I and isn't something that's charged.

> This would be real power from energy stored (but constantly moving) on
> the 1/2 wavelength line so long as the system is active. We know we

> time plot (viewed as a "standing wave" on the time plot).

The existence of both voltage and current at any point along the line tells us that there is instantaneous power at that point, which means that energy is flowing past that point. At any point along the open circuited line except the ends and middle (where the power is always zero), we can see that the power is in the form of a sine wave having twice the period of v(t) or i(t) and no offset. This means that at any point, energy flows first one direction, then back, equal amounts and for equal amounts of time, twice during each v(t) or i(t) cycle. The result is no net energy flow in either direction.

It's sad to see that the response to my analysis and equations is insult and derision rather than any coherent counter argument, but I'm unfortunately not surprised. I don't see in it any evidence that my posted calculation was in error -- the only objections I see are that it doesn't support a flawed theory, so it therefore must be wrong. The calculations I made are based on solid theory which has been successfully used for more than a century, and you won't be able to make any measurement which will refute them. They're also entirely self consistent with all other transmission line phenomena which can be calculated or measured.

So I wouldn't bother to respond at all except that it does provide the opportunity to elaborate a bit on what I posted. If further responses are as devoid of substance as this one, I'll probably end up plonking Dave as I did Cecil some time ago, for the same reason.

Dave wrote:
> so roy has correctly calculated the standing wave 'power' to be zero at two
> points on the line. i am sure that yuri will take great exception to this
> result showing there is no power in the standing wave.

I did what I claimed to be able to do -- correctly calculate the power from v(t) * i(t). Yuri takes exception to many things I say, but frankly that bothers me not in the least.

> but he missed the definition of pr and pf...

Indeed I did. Can you define them for me please?

p(t) = v(t) * i(t)
v(t) = vf(t) + vr(t)
i(t) = if(t) + ir(t)

Therefore,

p(t) = [vf(t) + vr(t)] * [if(t) + ir(t)]
= vf(t) * if(t) + vr(t) * ir(t) + vf(t) * ir(t) + vr(t) * if(t)

Of these four terms, which, if any, are pf(t) and pr(t)? What are the two remaining terms called?

> dave in problem statement:
>> now, calculate vf(t), if(t),pf(t), vr(t), ir(t), pr(t) at that point,
>> where
>> the 'f' terms are the forward wave, the 'r' terms are the reflected wave.
>
> so he conveniently skipped that step and instead writes this cop out:

No, I did calculate all except pf(t) and pr(t), which you didn't define.
As soon as you do (see the question above), I'll be glad to calculate
them also. Or you could do it for us -- it won't involve more than
simple arithmetic.

> roy:
>> I haven't seen a definition of pr and pf, but they're not relevant to

>
> pr and pf are, as i stated, the power in the forward and reflected waves.

What would that be, then, vr(t) * ir(t) and vf(t) * if(t)? Where does
the power in those remaining two terms come from or go?

> There is of course power in these two waves and it is indeed 'sloshing' back
> and forth in the line.

Please note that I didn't say that power was "sloshing" back and forth.
I said that energy was. Power is not the same as energy -- they bear the
same relationship as speed and distance.

Unfortunately, people assume that the units indicated on a meter are the
quantity actually being measured, which often they're not. But this has
been explained many times before here.

> those points.

Here's just one of the problems with assigning powers to the traveling waves, attempting to keep track of them separately, and applying superposition to nonlinear quantities. The conclusion that there is power at the ends of the line, for example, is demonstrably not true. There is no current at the far end of the line at any time, and therefore no power, as I showed. My comment at the end further shows why the power at the end of the line must be zero.

> and then he has to end up with an obvious contradiction:
>
>> indicating the movement of energy back
>> and forth but no net energy flow.
>
> how does energy not flow if it is moving back and forth???

Hopefully most of the readers were more astute than this and noticed the word "net". If equal amounts of energy flow in each direction during a cycle (as indicated by a power waveform with no offset), there is no net energy flow. It means that energy is being stored at some location in one direction, then returned during the other half of the power cycle. This is true in any purely reactive circuit, for example a tank circuit, where exactly the same calculation I made can be done with the same result.

Consider our open ended line for a moment, and imagine it laid out from left to right with the open end to the right, so I can name directions. There's no place to the right of the line to store energy, so no energy can be moved past that point to the right. If we consider the positive direction of energy flow as being to the right, this means that the power at the end of the line can never go positive, even for an instant -- if it did, it would mean energy is moving past the end of the line during that time. But since there's no storage mechanism beyond the end, this can't happen. And since we can't have net energy moving past the end, either, the power therefore can't go negative at any time either. So the power at the end of the line must be zero at all times. This is of course the result I got from v(t) * i(t).

> not standing waves.
> --
> 73, Cecil http://www.w5dxp.com

Love those absolute statements, just like my mother in-law used to say:
"because..."

So can we take it apart?
I have a quarter wave resonant, fine tuned, coil loaded Hustler mobile 80m
whippy.
So far we knew that it is a standing wave circuit. Now Cecil tells me that
it automatically becomes traveling wave in/through the coil? Wasaaap?
Christmas miracle?
We know, saw burning and measured that current decreases towards the top as
proportional to the standing wave (current). We know that traveling wave has
uniform current along the conductor (coil). That it needs to be terminated
in characteristic impedance load somewhere in order to have nice smooth
constant current distribution along the conductor (antenna).
So far I have learned that, yes, standing wave current can burn the coil
(now it is traveling), that sw voltage can burn lossy insulator and create
corona. That current through resistance generates heat, consumes real power.
That resonant antenna is a standing wave circuit, but standing wave voltage
and current, while they are measurable and observable do not have (sw)
power. When I pump more power to the antenna, it burns faster. It takes
power to burn things, but there is no power, just current and voltage.
Normally power is voltage times current, but not in Hustler country. (Use
lossless transmission line, dummy :-)

"You are right Yuri (finally) because......."

So what happened to collapsing E field creating M field and them 90 degrees?

How can I proceed to explore standing wave antennas vs. traveling waves if I am stuck here on the Hustler whip and its whims and "no power" burning coils?
Must be the messed up equilibrium somewhere :-)

Huh?

Yuri

I made an error int he above statement which I need to correct.
The particles used in the transition from Gauss are STATIC particles
of the inter galaxial kind which have the propensity to settle on
diamagnetic materials without rejection This being the same material
from which antennas are made of. When a majority of free electron
are in a ELECTROSTATIC field created by a change in voltage levitation
takes place on static particles. This is somewhat opposite to
ELECTROMAGNETIC levitation altho there are also other differences
which I need not to go into at this time. The circuit that providees
such conditions is a tank circuit where the radiator must be a
multiple
of one wave length to ensure equilibrium is maintained within
the Gaussian field

Now, let me see, to sum that "all up:"

1) Do not think for yourself; only thoughts which have gone before are valid.

2) There is nothing which has been overlooked in prior works.

3) The world is only composed of idiots; if they even read the conversation/debate of others on "possibilities" their lack of mental prowness will be their end.

4) If someone doesn't have a complete and absolute understanding of the "truths" at this point, so be it, they are not to engage in any discussions which will expose their ignorance--else they be less than REAL men/women.

5) Etc., etc., etc. ...

Yeah, I have heard it all before ... thanks. Frankly, if there does exist such idiots as you propose--so be it.

THREAD PLONK!

I see we are back to the old business about colliding waves that apparently carry vector power. At least it seems that way since the counter-traveling power can cancel at some points and add up at other points. I thought we trashed this idea a couple of years ago.

Remember, calculate fields first and then worry about power or energy. Any change in that calculation order will surely lead to "traveling waves of average power" and other such gems.

I hope no Joules are hurt in the collision.

If two boards of a length are secured upon the surface of a body of water, their parallel distances to each other computed to "contain" "standing waves" of a certain frequency, and a device to "impart energy" placed against one, to "strike" the surface of the water--much can be seen without the necessity of "complicating maths."

Or, a substantial mud puddle, two boards and a timing circuit ...

Roy, God Himself appeared to me in a vision and said that
if you don't stop bearing false witness against me, you are
going to end up in a very bad place.

For the record, here's what I said in a WorldRadio article
more than three years ago: "The author has endeavored to satisfy
the purists in this series of articles. The term "power flow" has
been avoided in favor of "energy flow". Power is a measure of that
energy flow per unit time through a plane. Likewise, the EM fields
in the waves do the interfering. Powers, treated as scalars, are
incapable of interference. Any sign associated with a power in
this paper is the sign of the cosine of the phase angle between
two voltage phasors."

> The existence of both voltage and current at any point along the line
> tells us that there is instantaneous power at that point, ...

Not if the voltage and current are always 90 degrees out of
phase which is a fact of physics for pure standing waves. There
is no power, instantaneous or otherwise, in pure standing waves.
The cosine of 90 degrees is *always* zero.

snip-

You can't do that unless you break up the rise in voltage from
beginning to end
in segments. Each segment is different to the other when you are
considering
a tank circuit. This is why these arguments take so long, since one is
talking
about the fields at one segment and all the other corresponders are
refering
to other segments. It is quite possible that many correspondents are
correct
but only with respect to the segment they are referring to.You should
all
get on the same stage when entertaing such that the audio does not
get
to the deafining level while at the same time entertaining the same
audience

Dave:

1. I am responding to Art in caps only because when he posts from google.com, his posts do not have quote attributes (such as "<"). I am using IE6 which does not pick up such attributes. Thus, in responding to his paragraphs I need some way to differentiate his sentences from mine. I cannot use italics, clors or bold so my only choice is caps. I know that caps sometimes implies "yelling" but in this case that is not my intent. I am not going to manually insert quote attributes.

2. In reference to a "cheap troll", I believe it was you who started this thread.

Are you saying that you are starting threads in rraa with the intent of trolling for sucker posts?

No, that's not what I said. What I said is the voltage and
current in a standing wave are *always* 90 degrees out of
phase and it is impossible to generate heat when the voltage
and current are 90 degrees out of phase. Just as soon as
heat is detected, we know the cosine of the angle between the
voltage and current is 1.0 which tells us it is a traveling
wave, not a standing wave.

As long as the phase angle between the voltage and current
remains at 90 degrees, it is a standing wave, by definition,
and heat cannot be extracted. If heat is extracted, it no
longer meets the definition of a standing wave.

Reality can certainly contain illusions. Sunrise and sunset
are a couple of examples. Magician tricks are another.

If you want to prove that standing waves are not an illusion,
take away the component forward and reverse traveling waves
and show us what you have left. As I said above, to which
you objected, standing waves cannot exist independently
of their forward and reverse components. I stand by that
statement. Prove it wrong if you can.

Please cease the obfuscation. It cannot be explained any
better than these two web pages. Please note that "intensity"
is a power density (watts/unit-area) and it is *energy* that
is redistributed, not voltage or current.

www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and the
thickness of the film are such that a phase difference exists
between reflections of p, then reflected wavefronts interfere
destructively, and overall reflected intensity is a minimum.
If the two reflections are of equal amplitude, then this
amplitude (and hence intensity) minimum will be zero."
[Referring to 1/4 wavelength thin films.]

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity
will appear as enhanced intensity in the transmitted beam. The
sum of the reflected and transmitted beam intensities is always
equal to the incident intensity. This important fact has been
confirmed experimentally."

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in
these waves must somehow be recovered or redistributed in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are redistributed to regions that permit
constructive interference, so the effect should be considered as
a redistribution of light waves and photon energy rather than
the spontaneous construction or destruction of light."

The logic in your argument is flawless, in fact, I believe it ...

However, the voltage/current/power/energy/joules given out by my car alternator cannot exist independently of the petrol powered motor. Still, I consider that electrical voltage/current/power/energy/joules a "SEPARATE entity" ...

Yanno, he didn't come last night ... the cookies and milk still sit before the hearth, no unaccounted gifts clutter the space beneath the tree ... yet still, I believe! :-P

Let me clear this up a bit further because of the related posts

Articles that refer to frogs elc being levitated are refering to
the magnetic field of 1 to 10 tesla where the leviatated
material diamagnetic.
Articles refering to the electron gun should realise that the
electrons are
not in the majority and in fact the electrons are part and parcel of
the
material being heated by being in orbit. It takes considerable power
to remove the electron from orbit from its native material and like a
tungsten lamp dissapates over time which when DC is used is called
"notching"
The same thing happens of course when heating is done by AC except we
have
two notches in different places instead of one which is why DC driven

lamps only have a half life.
So let me reiterate.In a electron gun the electron is torn away
from its orbit which diminishes the mass of the parent material.
With respect to a passive or static particle the particle is
levitated from a diamagnetic surface beyond the arbitary Gaussian
field
where when the electrostatic field diminishes the surface is
repopulated. That is if the operation is not in a vacuum!
Ofcourse some particles are already in motion when the electrostatic
field dissapates such that some particles have not had time to escape
the arbitary field, so I suggest these return to the diamagnetic
material
where all the surface space has now been taken by replacement static
particles thus leaving only the space below the surface for them to
rest and decay.
I hope that makes things clearer.
Regards
Art Unwin KB9MZ.....xg

These comments in total are very interesting, by both authors. Thank you for them.

It is clear that there is not a standard way of describing energy that is in the process of being stored in either an inductor or capacitor. Clearly it is stored, not used (converted) as in a resistor.

Storage of energy in a capacitor (for instance) occurs over time and requires power to complete. So how do we describe that power if it is always zero because voltage and current are 90 degrees out of phase? Should we recognize that only the peak voltage and peak current is 90 degrees out of phase, with the entire charging time occurring within those two time extremes? Between those two time extremes, the voltage and current are in phase but at changing impedance, with power flowing into the capacitor. So think I.

I think of the "standing wave" as being equivalent to the graph on my power bill that shows power used daily over a month. Granted that the standing wave is recorded in V or I, but we only need to know the R that the standing wave is acting through to determine the power that it represents.

I certainly find this interesting.

Here's how power engineers solve the problem.
Voltage and Current are phasors.

V*I = volt-amps

V*I*cos(A) = Watts, real power

V*I*sin(A) = VARS, reactive power

The standing wave is completely reactive. It is constantly storing and releasing energy. In addition to the standing wave we have ohmic resistance in series and radiation resistance in parallel. For the series ohmic resistance and parallel radiation resistance, current is in phase when the antenna is resonant. Think of a circuit with a capacitor, inductor and radiation resistor resonant in parallel with an ohmic reistor in series with the RLC. The standing wave portion is drawn by the capacitor/coil where current through the inductive portion is lags +90 degrees wrt to voltage and through the capacitive it leads by 90 degrees. The standing wave is merely a vibrational energy shift between antenna system inductance and antenna system capacitance. However, the impedance of the total circuit also consists of real components accounting for the real power drawn by your residential electrical service (or car battery). For this portion of the antenna, the current is a travelling wave. Hopefully, radiation resistance will be >> ohmic but that will not usually be the case with a bug catcher.

I keep reading this stuff looking for a complete definition of this new
"standing wave" that has a life of its own.

A whole lot of the quote is inconsistent, but lets just examine this
little sentence:
> ... The standing wave is merely a vibrational
> energy shift between antenna system inductance and antenna system
> capacitance. ...

Let's consider a 50 ohm ideal transmission line with a 25 ohm ideal
resistive load in the AC steady state. There is no "antenna system
inductance and antenna system capacitance", there is no load inductance

or capacitance at all.

Now is there a "standing wave" on the transmission line in the absence of these elements that are purported to underly "a vibrational energy shift between antenna system inductance and antenna system capacitance"?

Of course there is... well, at least in terms of the conventional meaning of "standing wave", so this explanation of what underlies a standing wave must be flawed.

Owen

I suspect what Dan is referring to is the LCLCLCLC
equivalent circuit for a transmission line. A horizontal
wire over ground is a one-wire transmission line with
Z0 = ~SQRT(L/C). A radiating antenna can be considered
to be a lossy transmission line.

A #14 horizontal wire at 30 feet calculates out to be
Z0 = 600 ohms so L/C = ~360,000. I'm pretty sure that
is the L and C that Dan is talking about - the same
L and C in which the standing wave energy is stored.

You can believe that the sun rises and sets if you want to,
Dave. Most of us know that the sun is fixed at the center
of the solar system. The names "sun rise" and "sun set" were
coined back when humans believed that the sun actually made
a trip across the sky every day over a flat earth. Do you also
believe in a flat earth?

> must be flawed.

No, it is not flawed:

1. Transmission line: In terms of mathematics, the impedance of an arbitrary length depends on the Zo, the length and the frequency. Of course, the equation is rather arithmetically onerous, containing complex components so let us use the smith chart. Since you did not specify a length, it is slightly easier to choose a 1/4W resonant line although there would not be a big problem using say 80 electrical degrees of line (perhaps you might like to try that).

On the smith chart, you have provided Zo = 50 ohms and Z(L) = 25 + j0 ohms. Draw the SWR circle from the compass point at R = 25/50 = 0.5 or SWR = 2.

As you move around the circle, you can directly read the impedance from generator towards the load at R = j0 with gradually increasing values of capacitance depending on where you are in the line. At 90 degrees electrical, Z = Zo(0.5 - j0.86). When the wave is reflected back, now you go back towards the generator and you see an inductive impedance Z = Zo(0.5 + j0.86) gradually decreasing as you go back to the generator. So you very definitely have energy stored and released, stored and released as the forward and reflected waves traverse along the line. In your case, you also have 25 ohms resistive which is being dissipated. Since your SWR is 2, the amplitude ratio between forward and reflected is not 1:1. If you refer to the external scale on the chart, the difference in amplitude between forward and reflected waves is at SWR = 2 is 6dB.

2. Antenna: The same principles apply except that the inductive and capacitive components are not distributed in the same linear way as in the transmission line. It really doesn't matter; all of the above information gleaned from the smith chart remains the same for an antenna.

Now, I could have gone into the complex equations and filled 3 sheets of paper with calculations but I chose to let the smith chart do the calculating for me (as any sane person would!). But you can also see that there are differences between the antenna and your transmission line example and my lumped component example but they only exist in terms of how you conceptualize the 'system'. The principles hold true in all cases.

Typo correction:

"As you move around the circle, you can directly read the impedance from generator towards the load at R = j0 with gradually increasing values of capacitance depending on where you are in the line."

Should be "...towards the load at R = 0.5 - j0".

Yes, thanks Cecil, that is exactly what I mean. In the xmission line, the L's and C's are evenly distributed and in the antennas they are not so nicely linear. The antenna is a lossy transmission line just as Owen's example was a lossy xmission line example with a 25 ohm load at the end. In this case, antenna, xmission line and lumped components work out the same. The inductance stores the current and the capacitance stores the voltage with the power being imaginary (reactive VA) in the standing wave portion. You could keep the standing wave going forever with 0 watts real power being inputted if there were no ohmic or radiation resistance dissipating the power.

I put to you a scenario where there was no antenna or load inductance or capacitance, and there was a standing wave on the transmission line.

That says to me that the standing wave is not a consequence of antenna or load inductance or capacitance, or "a vibrational energy shift between antenna system inductance and antenna system capacitance" as you put it.

Owen

Why does that not imply a reactive standing wave, which is what I mean by "a vibrational energy shift between antenna (transmission or lumped) system inductance and antenna (transmission or lumped) system capacitance". Vibrational simply means a wave. I use the word "vibrational" as part of the conceptualiztion of energy going back and forth. Just because you also have real power dissipation does not mean you do not have a reactive component as well. You have both. Your SWR = 2 was due to the 25 ohm impedance. If you had given me 50 ohm impedance at the end of the 1/4W transmission line, your SWR would = 1 and you would only have a travelling wave with no power being reflected back to cause a standing wave. All power would be absorbed by the 50 ohm resistor. If you had said the line were open, then you would have a 1:1 SWR in a 1/4W resonant system with no preal power being absorebed by the inite ohm resistor. The higher the SWR on a transmission line of 1/4W resonance or any length, the more travelling wave component you have and the less standing wave component you have since the attenuation between transmitted and reflected waves becomes too great.

since:
2b
L = 0.00508((ln---) - 0.75) (best ascii can do)
a

where:
L = uH
a = wire dia in inches
b = wire length in inches
ln = natural logarithm
and, since #14 is .0641 inch
and 30 ft = 30*12 or 360 inches

2*360
L = 0.00508((ln(------)) - 0.75)
0.0641

L = .043568935605uH

Now, if I can just find that formula for the capacitance of a free wire
in space--I know I seen it here just a bit ago ... sorry, I'll have to
get back to you on that one ;-)

Regards,
JS

No, my example stipulated an ideal transmission line, and by that I mean it
to be lossless amongst other things.

You and Cecil are transforming the example to suit yourselves.

Owen.

Sure there is. The energy stored in a capacitor is 1/2 * C * V^2, and in an inductor, 1/2 * L * I^2. The rate of energy flow into or out of an inductor or capacitor is called "power". It's exactly the same stuff as energy moving into or through a resistor, and it's measured and described in exactly the same way.

> Storage of energy in a capacitor (for instance) occurs over time and
> requires power to complete.

Yes, power is the rate of energy transfer.

> So how do we describe that power if it is
> always zero because voltage and current are 90 degrees out of phase?

See the following example which shows just that situation.

> Should we recognize that only the peak voltage and peak current is 90
> degrees out of phase, with the entire charging time occurring within
> those two time extremes? Between those two time extremes, the voltage
> and current are in phase but at changing impedance, with power flowing
> into the capacitor. So think I.

The whole concept of impedance gets a bit flaky when working in the time domain. I recommend sticking to voltage, current, power, and energy when doing so. Go through the following example, and I believe you'll get a much better idea of what's happening on a basic level.

But you've made some good observations. The answer is that, as I mentioned, the instantaneous power (p(t)) is not zero except at the ends and middle of the example line. Some of the posters are confusing average and instantaneous power, which is leading to incorrect statements and conclusions. Instantaneous power can easily be non-zero while maintaining zero average power, as I'll illustrate.

Let's look, for example, at the half wavelength open circuited line described by "Dave", being driven by v = 0.5 sin(wt), 1/8 wavelength from the end. At that point,

vf(t) = 0.5 sin(wt - 135 deg.)
vr(t) = 0.5 sin(wt - 225 deg.)
if(t) = 0.01 sin(wt - 135 deg.)
ir(t) = -0.01 sin(wt - 225 deg.)

considering the positive direction of ir(t) as the same as the positive direction of if(t) so we can add if(t) and ir(t) to get i(t).

Using elementary trig identities for the addition, and dropping the explicit identification of degrees for simplicity:

vf(t) + vr(t) = v(t) = sin(wt - 180) * cos(45) = 0.7172 * sin(wt - 180)
if(t) + ir(t) = i(t) = 0.02 * cos(wt - 180) * sin(45) = 0.01414 *
cos(wt - 180)

One important thing to notice is that, unlike the ends or center of the line, neither the voltage nor the current is zero at this point. Consequently, their product is also non-zero.

The voltage and current are, of course, 90 degrees out of phase, as they are everywhere along an open circuited or short circuited line, or one terminated in a pure reactance. And when the average power is computed from the instantaneous power, the result will be zero. But that doesn't mean that the instantaneous power is zero as some are claiming. Let's see what it does mean. Using another trig identity,

p(t) = v(t) * i(t) = 0.01 * sin(wt - 180) * cos(wt - 180)
= 0.005 * sin(2wt)

This is the instantaneous power which, as I've described before, is a sinusoidal function with rotational frequency 2w. It has no offset, so the average value is zero. But it shows that energy moves back and forth past this point every cycle. Equal amounts move each direction each cycle, so no net power flows either direction.

There are simpler ways to get the same answer, but this one shows very basically where the energy is going at every instant. If instead you start out by throwing away the time information and just looking at averages, you lose a lot of information along with the basic understanding of energy movement in the system. I'm afraid some people have taken this simpler approach without realizing what information and insight they've lost by doing so. The average value can always be determined from the instantaneous function, but never the other way around.

> I think of the "standing wave" as being equivalent to the graph on my
> power bill that shows power used daily over a month. Granted that the

> the standing wave is acting through to determine the power that it
> represents.

Not quite. The power bill graph is a graph of the power, much like the p(t) function I calculated. The energy, which you pay for, is the integral of that graph. If you used a constant power of 1 kW for half the month, then sent 1 kW back into the power grid for the other half of the month, you'd technically owe nothing, since you'd use no net power. You might even have stored it somewhere and given the very same energy back rather than using some and generating an equal amount later. That's exactly what's happening at the point on the line 1/8 wavelength from the end.

Roy Lewallen, W7EL

-- I've had many opportunities when doing this to make arithmetic or trigonometric errors, and I haven't taken the time to thoroughly check my work -- although the conclusion is correct. I'd appreciate anyone pointing out any mathematical errors he's found.

Not if the voltage and current are always 90 degrees out of
phase which is a fact of physics for pure standing waves. There
is no power, instantaneous or otherwise, in pure standing waves.
The cosine of 90 degrees is *always* zero.
--
**8

Cecil, your technical and mathematical skills vastly exceed mine... My
poor little monkey brain has to work in the concrete, not the
abstract...
I sort of understand the concept of the standing wave being the
instantaneous vector product of two colliding EM wave fronts...
I accept the fact that MATHEMATICALLY; P = V*I* cos (theta).... And
being that theta is DEFINED as 90 degrees the cos = 0, so the
instantaneous power is zero...
But here is where the math breaks down...
On my herd of 100KW RF generators... Every time the load failed for
even a split second, those fire breathing dragons would blow a hole
through the quarter inch thick slabs of copper that made up the line,
instantaneously...
To prove that mathematically there is no power contained in a standing
wave collides with my, farm boy, real world, physics experiments...
The voltage peak on that line when that standing wave forms is real,
it has mucho power (esp when driven by the dragon breath of a 100KW
triode with 15KV on the plate), and it blows the hole in the line at
the same distance from the load every time (proof of standing wave
theory)...

This is why i have a problem accepting that a standing wave contains
no power - regardless of the prominence of the men who wrote the
textbooks..

cheers ... denny

Same here, I burn the coil with "no power" on standing wave circuit -
quarter wave resonant loaded whip.
Cecil is telling us that the current becomes automatically traveling wave,
while EZNEC model shows drop along the coil and rest of the circuit with
nice standing wave.
I grew up in the city, around cars and I am having problem swallowing that
we have SW current and voltage but no power, while we pump power into the
circuit and see nasty things happening requiring power.

three cheers... Yuri oK3BU

In that case, the standing wave is contained in the inductance
and capacitance in the transmission line.

> That says to me that the standing wave is not a consequence of antenna or
> load inductance or capacitance, or "a vibrational energy shift between
> antenna system inductance and antenna system capacitance" as you put it.

When Dan said that, he was not talking about transmission lines.
He was talking about the standing wave antenna itself (without
the transmission line). You two are talking about entirely
different things.

Sunrise and sunset are simply names we've given to that which you've described. My logging program provides me with sunrise and sunset times for various parts of the world. The National Weather Service uses those terms. You may choose to say at the beginning of each day that the earth has rotated so that the star at the center of our solar system is visible. I don't know anyone who spouts that kind of mouthful.

> to be lossless amongst other things.

What we are saying is that even if the transmission line
is lossless, the *system* is lossy because of the 25 ohm
resistor.

If there were no losses in the *system*, the waves on the
lossless transmission line would be pure standing waves.
Because of the losses in the load, the waves on the lossless
transmission line are not pure standing waves, but a mixture
of standing waves and traveling waves. In your case (#1 below)
the system is primarily a traveling wave system, closer to
flat than to an OC or SC stub because only 11% of the forward
energy is rejected by the load.

> You and Cecil are transforming the example to suit yourselves.

I'm not transforming the example. You are the one who put
the lossy resistor in the system. The traveling waves are
the direct result of the installation of the resistor.

Let's look at a few different examples and assume the
measured joules/sec flowing forward toward the load is
100 joules/sec in each case.

1. Your example of 50 ohm lossless coax connected to a 25
ohm load. The forward joules/sec is 100. The reflected
joules/sec is 11.11. The joules/sec consumed by the 25
ohm load is 88.89. 89% of the forward wave is traveling
wave. 11.11% of the forward wave is used by the standing
wave. The system is primarily a traveling wave system.
The energy not delivered to the load is stored in the
standing wave in the LCLCLCLC components of the
transmission line.

2. No load on the lossless coax. The forward joules/sec
and the reflected joules/sec are equal. 100% of the energy
is standing wave energy and all of it is stored in the
LCLCLCLC components of the transmission line. It does not
move from LC to LC. It simply oscillates in place between

L and C. EZNEC confirms that the current phasor does NOT rotate.

3. 50 ohm load on the lossless coax. The reflected joules/sec equals zero and the system is flat. 100% of the energy is traveling wave energy. The only energy in the transmission line is the energy it took to fill the pipeline, the delay between power-on and the load dissipating power. The LCLCLCLC in this case is an energy bucket brigade.

4. 500 ohm load on the lossless coax. Of the forward 100 joules/sec, only 33 joules/sec is accepted by the load. The other 67 joules/sec are rejected by the load and become half of the energy in the standing wave. The system is primarily a standing wave system. The energy not delivered to the load is stored in the standing wave in the LCLCLCLC components of the transmission line.

You have just contradicted yourself. There *cannot* be any
real power associated with a voltage and current that are
90 degrees out of phase.

Power = V*I*cos(90) = 0 watts

I will attempt to check your math. I'll bet your dimensions
are volt*amps and NOT watts.

> On my herd of 100KW RF generators... Every time the load failed for
> even a split second, those fire breathing dragons would blow a hole
> through the quarter inch thick slabs of copper that made up the line,
> instantaneously...

The math didn't break down, Denny, your logic did.

1. The standing wave voltage is *ALWAYS* 90 degrees out of
phase with the standing wave current, by definition.

2. It is *IMPOSSIBLE* to "blow a hole through the quarter
inch thick slabs of copper" with a voltage and current that
are 90 degrees out of phase.

3. Therefore, the voltage and current that blew the holes
in the copper slabs were NOT 90 degrees out of phase and
therefore were not standing waves. In-phase voltage and
current is required to blow holes in copper slabs.

4. Standing waves are a steady-state phenomenon. Blowing
holes in copper slabs is a transient phenomenon. At the
end of steady-state, the standing wave energy is always
converted into real watts and either radiated or dissipated.

The energy that blew holes in your copper slabs did NOT
meet the definition of "standing wave energy". During
the transient state, it was converted from standing wave
energy (with its 90 degree phase difference between voltage
and current) to traveling wave energy (with its in-phase
relationship between voltage and current).

Yes, it is impossible to get any watts out of a voltage
and current that are 90 degrees apart simply because
there are zero watts available.

Standing wave voltage and current are 90 degrees apart,
by definition.

Therefore, by definition, any wave that yields watts
is NOT a standing wave.

Those are not watts, those are volt*amps. Therefore that's
not real power. Real power is:

p(t) = v(t) * i(t) * cos(90) = ZERO

Food for thought
About ten years ago a sattelite generated a barium
(diamagnetic) cloud in space. When this cloud was
penetrated they found a cavity inside where there
was an electric field in which there was current flow.
This does not state that the return current actually
flows thru the inside of a radiator, only that current
flow is possible on the IINSIDE of a diamagnetic
material.

So then shouldn't one expect coax to be heated uniformly along its
length at a high SWR?

Thanks Cecil.

When discussing the typical amateur operator's transmission system, one cannot isolate three configurations that contain reactive components. The typical amateur operator has a tuner, which conforms mostly to the lumped model. Then there is the transmission line which of course complies with the transmission line model. And then we have the antenna which conforms to a lossy transmission line model due to radiation resistance (even is we assume ohmic R = 0).

My setup is typical; I have a 50 ohm transceiver connected to an ameritron AL80B that has 50 ohm input impedance (matched in part using lumped components). The linear output goes to a 3KW 'tuner' and SWR/power meter which connects to a G5RV antenna system whose dimensions conform to the space in my attic (it is a somewhat large attic). I have a lumped 1:1 'ugly balun between the unbalanced 50 ohm coax and the balanced ladder line that feeds the antenna.

When I 'tune' to SWR =1:1, there is a standing wave in the entire system. The amplitudes of the forward and reverse waves through the whole are the same (not attenuated). There is a back and forth vibration that involves antenna capacitance/inductace, 2 different transmission line capcitance/inductances, capacitance and inductance manually adjusted in the tuner and the discrete lumped components at the xcvr output, and amp input and output. This standing wave exists but it does *nothing* to transmit power from my amp into radiated power. My tuner does not get 'hot' when I

key down (except for perhaps some ohmic losses). What gets hot are the clouds above my house ;-) due to the radiation resistance that transmitted a TRAVELLING wave into real radiated power.

When discussing a bug catcher, the discreet inductor component also functions partially as the antenna and together with the phase shift of the impedance discontinuity between the stinger and coil makes up part of the electrical length of the antenna. In my case, electrical antenna length consists of the antenna itself, phase shift at ladder line/antenna discontinuity, radiating ladder line, impedance discontinuity at the tuner and so on. Hopefully my tuner, ugly balun coax are not a significant part of the electrical length of the antenna.

My point is that we must be able to discuss all 3 models (plus impedance discontinuity shifts) to obtain a full understanding of antennas. It is imperative that we are able to separate the reactive power from real power. Think of a car stuck on an icy road; two people push up and down on the back of the car at mechanical resonant frequency. Once that up and down motion is in process, it takes very little effort to keep the vibration going. That is reactive power. Then the two people push in the forward direction and the car moves. That is the travelling wave portion that takes real power.

No, on a lossless wire or transmission line with pure
standing waves, at any *PLANE* intersecting the wire or
transmission line, the measured net voltage will be 90
degrees out of phase with the measured net current.

Vtot(t) = Vfor(t) + Vref(t) and |Vfor|=|Vref|

Itot(t) = Ifor(t) - Iref(t) and |Ifor|=|Iref|

The negative sign on Iref(t) puts Itot(t) 90
degrees out of phase with Vtot(t). You can easily
prove that for yourself.

By definition, there cannot be any real average or
real instantaneous power (watts) in a standing wave.

Cecil, I think this is an excellent series of examples, and greatly helps me understand your thinking. Roy also wrote a great posting, which I will respond to shortly.

But I wonder if you are thinking of the standing wave as the end of the reflected wave, or as the envelope described by the reflected waves as they sequence in time. These choices at first sound nearly identical, but they are not. A sequence of reflected waves results in sequential changes that affect the input power. The final standing wave will not be defined until several sequential waves have occurred. Unless adjusted, the ongoing stable power flow to the load will be reduced (or increased) from the initial value by the effects of the standing wave. So think I.

Thanks for this series of examples.

No, any and all heat is work done by traveling waves, not
standing waves. As long as standing waves exist as standing
waves, they are incapable of doing work or heating anything.

You, of all people, should appreciate that since V*I*cos(90)
equals zero for standing waves, absolutely no work can be
performed by a standing wave. If the energy in a standing
wave is used to provide work, the standing wave ceases to
exist as it does at key-up.

In trying to get any work out of V*I*cos(90)=0, blood out
of a turnip comes to mind.

Just a Nit.

The standing wave does do something to help the process.
It, like the tuner, transforms impedances. Without the
impedance transformation properties of the standing
waves, the system would not work as designed.

With my All-HF-Band notuner dipole (on my web page) the
standing waves are my friends, not my enemies. Without
the standing waves, my ladder-line length selector
method of matching would not work.

Roy, thanks for this posting and it's immediate predecessors. They are very helpful both to my understanding and toward understanding how you are thinking of things.

Your comment about the power bill was particularly helpful because you are exactly right about the sequence of power, first received, and then given back. The standing wave is doing exactly that, with the only difference being that power is moving from one side of the system to the other, with one side containing "negative power" (negative only in the sense that polarity is reversed) and the other positive power.

This does raise the question of the description of the traveling wave used in an earlier posting.

The example was the open ended 1/2 wavelength transmission line, Zo = 50 ohms, with 1v p-p applied at the source end. The term wt is the phase reference. At the center of the line, (using the source end as a reference), you gave vr(t) =-.05*sin(wt-90 deg.) and ir(t) = 0.01*sin(wt-90 deg.)

By using the time (wt-90), I think you mean that the peak occurs 90 degrees behind the leading edge.

This posting was certainly correct if we consider only the first reflected wave. However, I think we should consider that TWO reflected waves may exist on the line under final stable conditions. This might happen because the leading edge of the reflected wave will not reach the source until the entire second half of the initial exciting wave has been delivered. Thus we have a full wave delivered to the 1/2 wavelength line before the source ever "knows" that the transmission line is not infinitely long. We need to consider the entire wave period from (wt-0) to (wt-360.

If these things occur, then at the center of the line, final stable vr(t) and ir(t) are composed of two parts, vr(wt-90) and vr(wt-270) and corresponding ir(wt-90) and ir(wt-270). We should be describing vr(t) as vrt(t) where vrt is the summed voltage of the two reflected waves.

Then vrt(t) = vr(wt-90) + vr(wt-270) = 0
and irt(t) = ir(wt-90) + ir(wt-270) = 0

Below I will use the following terms:

vf = 1v/2 = 0.5v
vr = vf = 0.5v (for open circuit line)
ir = 0.5/50 = 0.01a

At the ends, vrt(t) = 2*vr(wt-90) = -2*vr(wt-270) = 1v

The voltage is doubled because of reflection. vf(wt-270) is negative.

Now consider power at the 45 and 135 degree points under stable conditions, 1/8 and 3/8 wavelength in from the source. This would be the power in the standing wave at the 45 and 135 degree locations.

At the 45 and 135 degree transmission line points, we have two components present because the peak of each wave will be in alignment with the leading edge of the reflected part of the same wave. (Reflected waves being reflected again) Peak current and peak voltage will be matched with near the near zero leading edge voltage and current.

Pr(left side) = vr(wt-90)*ir(wt-90) + vr(wt-180)*ir(wt-180)
= Pr(right side)= vr(wt-270)*ir(wt-270) + vr(wt-360)*ir(wt-360)
= 0.005w

Notice that vr(wt-90) and ir(wt-90) are different polarity from vr(wt-270) and ir(wt-270). but the products of v and i are positive.

Find total power in the standing wave at the 45 degree points from (ignoring the zero leading edge component)

Prt = Pr(left side) + Pr(right side)
= vr(wt-90)*ir(wt-90)+ vr(wt-270)*ir(wt-270)
= 0.005w + 0.005w = 0.01w

which is the total power (rate of energy delivery) contained in the standing wave at the points 45 degrees each side of center. If we want to find the total energy contained in the standing wave, we would integrate over the entire time period of 180 degrees.

So think I.

As you can see, by considering that a full wave or complete cycle may exist on the 1/2 wave transmission line, we can explain power moving from side to side over the transmission line. I could not have offered this explanation without your help and guidance and Cecil's as well. I hope you will agree that it is a correct analysis.

I am talking about steady-state and V(t) vs I(t) for
pure standing waves. Standing waves contain no real
active power. At the risk of having Jim Kelley develop
apoplexy :-) standing waves contain only reactive power,
as defined by The IEEE Dictionary.

I am not at the point where I would dismiss/cease-to-listen your argument(s), far from it.

However, I see no reason why standing waves on a string, standing waves in water, acoustic standing waves in the medium of a tuning fork, etc. should be expected to behave in any manner inconsistent to em waves in a medium--which can contain them and whereas standing waves will result ...

While most techs are "rote leaned", I am simply a hobbiest in these areas, I have no "indoctrinated beliefs."

It is pretty apparent where I would attempt connection with any of these mechanical waves in an attempt to extract work (power/energy/joules), and from any "container" capable of containing them.

I have no problem in forming questions about the validity of the math which drives your argument(s)--in one of my hands lays the formulas/equations, in the other what my eyes suggest--NO, "what my eyes tell me" ... close examination of either suggests the other is lie.

You will have patience if this takes a bit--I am sure ...

Got 'cha ...

I don't think anyone here would hesitate to offer assistance. However, for beginnings, the antenna should be cut for the specific freq of the mouse. Do you know that freq?

And then, without a schematic of the mouse, how would someone locate the "final amp" on the mouse with any certainty? Can you identify the trace/other which is serving as the ant now? That is where, most likely, you would make the connection. If it were my mouse I'd be more brazen--you hating me for making a wrong "guess" just doesn't cut it!

There is more to worry about also ... trust me.

Crux of the matter being--no one is a big hurry to help you "burn up" your mouse!

Another correction:

"When I 'tune' to SWR =1:1, there is a standing wave in the entire system. The amplitudes of the forward and reverse waves through the whole are the same (not attenuated)."

"There is a standing wave in the system from the tuner through the coax thru the ladder line thru the antenna".

For a static e field, of course, that would depend on the conductivity of the material. Barium being a metal would be a better conductor than, say, porcelain, another diamagnetic material. I doubt you would measure current flow across an electric field thru porcelain, unless the field were time varying.

Some of the "more to it" is that at 27Mhz, you are not going to add on anything I can think of which will improve distance--all I see is that you will detune circuit and antenna and degrade performance. (at least, in a usable way)

At 900Mhz and above, a complete antenna can consist of a "bread tie" and performance can be improved.

Let's see if any others have some thoughts ...

Regards,
JS

> varying.

I am not knoweledgable about those things but it does bother
me that it is accepted that the current on the antenna flows
up and then retraces its path on the way down.
For myself I do not understand why the flow is not down the
center within the underside of the so called surface skin.
For instance, if we had a half wave length surface then
the radiation would or should be equal to one full wave
length radiator. When I place a radiator inside a Gaussian
field it has to be near or at a full wave length to be resonant
and in equilibrium where the surface is what contains the
inductance and capacitance which are for the extremities of
movement for a parallel circuit and the return route must
be resistive only.
If I place one or more random length radiators of approx one wave
length with varying heights along its length into a antenna
program with an optimiser where it represents a gaussian
field,i.e. in equilibrium, the result will always be a non
planar array where the majority of elements are resonant
and at different angles and where the chosen fed element
drives all elements as one element by virtue of the array
being in equilibrium.Thus with varying heights the array
gets added gain but with a single feed point
If a half wave antenna is inserted initially that

would reflect the notion that the current travel was
2 X radiator length and thus the
array should consist of 1/2 wave radiators, which doesn't
compute!I.E resonant but not in equilibrium.
To me, this suggests that the return path is
down the center which is resistive only. My prior post
states that it is possible for current flow down the
center of a dimagnetic material which was the case
in a barium cloud.
From the above in then becomes logical that RADIATING
surface length is what counts and thus a helical antenna
must have a counter winding to be resonant AND in equilibrium.
So the main pont is, what exactly stops current travel down
the center of a radiator to conform with every day thinking?

My apologies for being not being completely clear.

My voltmeter is always one that is appropriate for the situation.
A d'Arsonval movement would work at sufficiently low frequencies
but for the ones under discussion an oscilloscope would probably
be more appropriate. It would be a voltmeter that would be able
to measure the actual voltage at a point on the line at a particular
time. I.e. V(x,t)

Again, apologies.

An excellent example.

Allow me to provide an alternate analysis.

The current between the black boxes is 0.

From circuit analysis theory, any branch with a current
that is always zero can be cut without altering the
conditions anywhere in the rest of the circuit.

Cut the branches connecting the two black boxes.

No conditions change in either of the now two cicuits.

It is obvious that the power dissipated in circuilator 1 must be provided by signal generator 1 and the power dissipated in circulator 2 must be provided by signal generator 2.

This is non-sensical. V(x,t) and I(x,t) are functions
representing the instanteous values of the voltage
and current with respect to place and time.

The expression you really mean is

Pavg = Vrms * Irms * cos(A)

You have to keep the time domain equations separate
from the phasor equations.

> If you write the above equation as:
>
> P(x,t) = V(x,t) * I(x,t)
>
> then you have implied the *dot product* of those
> terms.

No. I mean multiply the instantaneous value by
the instantaneous value, or more correctly,
the function representing the instantaneous
value of voltate by the function representing
the instantaneous value of current.

No vectors or phasors; just time domain functions.

At AC, it is established knowledge that skin effect takes place in round diamagnetic conductors such as copper and aluminum. Skin effect happens as a result of Lentz's law. From Lentz's law, foucault currents are set up to oppose the magnetic field of the AC current sent by the generator. The result is net forward current existing on the 'skin' of the conductor with a net reverse current inside the conductor. Think of the inside of the conductor as being occuppied by a current moving back towards the generator that sets up a magnetic field which opposes the magnetic field from the AC current sent by the generator. So you can see that indeed there is current flow through the center of the conductor; it will be a weak current but it is nature's attempt to oppose the change in magnetic field. I think the situation you are speaking to is having additional currents through the center that are additive (or subtractive) to the foucault currents. With proper material selection (such as mu-metal, a magnetic material of very high permeability), it may be possible to maximize the foucault currents themselves to nearly cancel the applied magnetic field (from the current in the generator). I believe it would be truely a pioneering effort to have center currents above and beyond this value, or cancelled, or even reversed. I would never say that it was impossible; after all, what is mu-metal but a material engineered and manufactured by man to increase its permeability several times and which has the effect of greatly reducing skin depth several times, thus allowing for maximum foucault currents even at low frequencies. Could this occur with diamagnetic materials as well? I will not say no. I am not sure if it has ever been tried. Could the complete mitigation of skin effect increase the velocity factor close to c in a vacuum? Maybe. What if you could actually reverse the skin effect? That gets into the things you are thinking about, i.e, smaller antennas. This is well outside the normal scope of thought but it is interesting to consider the 'what ifs' and that sort of thing does not violate Maxwell, it merely extends the applicability of Maxwell, Lentz etc..

The terms are used by meteorologists and scientists as well as laymen. Yet I know of no one who believes the Sun is moving across the sky. My logging program tells me both Sunset and Sunrise times for distant locations. It references no illusion. It simply uses those terms. What do you call the period when the Sun first becomes visible each day? What do you call the period at the end of each day, when the Sun ceases to be seen? Do you actually refer to the illusion of Sunrise or the illusion of Sunset?

> You seem to believe that illusions don't exist in

Thanks for the detailed response. A lot of new stuff
there for me to follow up on,a new word too.
The bottom line is how can one prove which path the
current takes when it reaches the top of an antenna?

In the 11m band the antenna can be extended simply by touching the antenna. This is because the human body is basically a saline conductive material and the size of the human body approaches 1/4 wave for these frequencies (that is why RF safety only allows 200 watts max at these frequencies). It might be worth a try to extend the antenna by using conductive material onto the surface of the mouse so it is possible for the user to touch the antenna input connection. This could improve the gain of both transmission and reception, that is, if it is actually in the HF 27MHz range

Have you considered the following possibility: A strip of mu-metal clad on both side to copper say 1 inch wide. Solder your connection from the transceiver directly to the outer claddings of mu metal in phase. Then solder a suitable capacitor or inductor to the inner copper diagmagnetic conductor. Apply 2X power to the reactance connected to the inner copper. Now you have an antenna with minimal skin effect. Increase the power throught copper to 3X; now you have net current flow thru the center diagmagnetic conductor. Maybe.

> generator 2.

Nope, that's not obvious at all. Make the signal generators
the same phase locked frequency with slightly different
modulation. The modulation for signal generator #1 will
appear across the load resistor in signal generator #2 and
vice versa.

A schematic shows exactly what is happening. There is no
path from SGCL1 to R1. There is no path from SGCL2 to R2.

```
SGCL1---1---2------2---1---SGCL2
\ / \ /
3 3
| |
R1 R2
```

There is nothing in the circuit to cause any reflections.
So the power dissipated in R2 comes from SGCL1 and the
power in R1 comes from SGCL2.

The leading edge and peak of what? The function sin(wt -90) looks exactly like the function sin(wt) except that it's delayed 90 degrees in phase. So the forward voltage wave is delayed by 90 degrees relative to the source voltage. This is due to the propagation time down 90 electrical degrees of transmission line.

Sorry, it's much worse than this.

Unless you have a perfect termination at the source or the load, there will be an *infinite number*, not just one or two, sets of forward and reflected waves beginning from the time the source is first turned on. You can try to keep track of them separately if you want, but you'll have an infinite number to deal with. After the first reflected wave reaches the source, its reflection becomes a new forward wave and it adds to the already present forward and reflected waves. The general approach to dealing with the infinity of following waves is to note that

exactly the same fraction of the new forward wave will be reflected as of the first forward wave. So the second set of forward and reflected waves have exactly the same relationship as the first set. This is true of each set in turn. Superposition holds, so we can sum the forward and reverse waves into any number of groups we want and solve problems separately for each group. Commonly, all the forward waves are added together into a total forward wave, and the reverse waves into a total reverse wave. These total waves have exactly the same relationship to each other that the first forward and reflected waves did -- the only result of all the reflections which followed the first is that the magnitude and phase of the total forward and total reverse waves are different from the first pair. But they've been changed by exactly the same factor.

It's not terribly difficult to do a fundamental analysis of what happens at each reflection, then sum the infinite series to get the total forward and total reverse waves. When you do, you'll get the values used in transmission line equations. I've gone through this exercise a number of times, and I recommend it to anyone wanting a deeper understanding of wave phenomena. Again, the results using this analysis method are identical to a direct steady state solution assuming that all reflections have already occurred.

The infinite number of waves could, of course, be combined into two or more sets instead of just one, with analysis done on each. If done correctly, you should get exactly the same result but with considerably more work.

I do want to add one caution, however. The analysis of a line from startup and including all reflections doesn't work well in some theoretical but physically unrealizable cases. One such case happens to be the one recently under discussion, where a line has a zero loss termination at both ends (in that case, a perfect voltage source at one end and an open circuit at the other. In those situations, infinite currents or voltages occur during runup, and the re-reflections continue to occur forever, so convergence is never reached. Other approaches are more productive to solving that class of theoretical circuits.

I haven't gone through your analysis, because it doesn't look like you're including the infinity of forward and reverse waves into your two.

Can not happen after cutting the branches.

And since cutting branches with zero current does not
alter the circuit conditions, it is not happening
before cutting the branches.

Or are you disuputing the validity of cutting branches
with zero current?

> can be attached to such a product.

When V(t) is the function describing the instaneous
voltage and I(t) is the function describing instaneous
current then

P(t) = V(t) * I(t)

is the function describing the instantenous power,
that is, the rate at which energy is being transferred
at any particular instant.

You can then integrate P(t) over the time of interest,
call it the interval from t0 to t1, divide by (t1-t0)
and obtain the average power for that interval. For
periodic functions, one period is an appropriate
interval to integrate over.

If you substitute
V(t) = Vpeak sin(wt)
I(t) = Ipeak sin(wt+alpha)
compute P(t), integrate and divide, you will obtain
Pavg = Vrms * Irms * cos(alpha)
which is how that convenient expression is derived.

It is worth doing to convince yourself. Then examine
P(t) to understand how the instaneous energy transfer
varies with time.

Even for a line without reflections, it is valuable
to understand that the energy flow is not continuous
but varies with a period of twice the frequency of
the voltage or current sinusoid.

4061. downward noise reducing ant?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-27 11:53:49 UTC
From: ml <m@di.net>
Message-ID: <m-E71A7E.06534427122007@news.verizon.net>
Source record: 30728

hi

I've been using a dipole antenna about 30ft each side connected to a sgc tuner with about 5ft of ladderline . this is mounted on my roof's elevator shack.

recently the elevator gear was upgrated to modern stuff and i've suffered with s9 steady but intermittant (sounds like noise level /background noise) 3min on 3min off like noise from 1-30mhz ever since it's mostly strongest from 1-7mhz and heavest on 80m

SO my building wo'nt let me get to crazy antenna wise but my question is

is there a type of antenna i could put up such that it would be very def below the antenna or something i could do that would accomplish this effect? and mitigate the interference perhaps??

would say a regular 3 element beam reduce the noise or just perhaps 'amplify' it how about a verticle w/ few radials? or something i am overlooking

my last choice and what i'd guess building wouldn't approve would be to put 2 receive only stearing verticles away from the elevator room not sure if that'd work technically but the other parts of the roof are off limits to me so i'd be a VERY hard sell but i wonder if that'd help or just ultimately be too noisy as verticles sometimes are

i don't have any other mounting locations nor any luck w/the elevator company

just looking for some suggestings

thanks all

happy holidays

Well, that is a tough situation...

On the antenna my first thought is a two element horizontal quad beam pointed straight up.... The reflector will tend to shield the driven from noise emanating from below... BUT, the noise being in the near field all bets are off and you will just have to try...
You might also try a phasing noise reducer, like the MFJ 1025, etc...
Again, the noise being all around you may be impossible to reduce, but then maybe not... Only a trial will tell...

You didn't mention the rig... Perhaps some DSP will help with reducing noise... Also going to narrow modes like CW <gasp, who does that ancient mode?> and PSK with narrow CRYSTAL filters will help...

In the end, you will likely have to team up with kindred souls and establsih a remote radio station operated the internet as your solution...

Roy, since you seem to know how to calculate the amplitude
and phase of the total current, please do that for different
points along the line and then explain how that constant
phase current can be used to measure the delay through
a 75m bugcatcher loading coil.

Dear Tehrasha Darkon and Group:

Yes! An additional curtain antenna is seen off to the right of the picture, which somewhat confuses. Additionally, the butterfly is not easy to see on the nearest antenna. Thank you for finding the picture.

Now, if the actual antenna people who have been on this group have not been driven off of the group by the theological ramblings about whether angels exist and, if so, how many could fit on the head of a pin, please enlighten this old antenna person who had thought he had seen every practical antenna (including a good many that were not practical - see US patent 1,554,231). What is the function of the groups of seven + butterfly?

Though I realize you might have been around at the time the terms were first used, it is evident that nearly all still use those terms today--even those in the scientific community. You keep writing, over and over, that the Sun just sits there in space. We both know that isn't actually correct either. The Sun rotates and is moving through space quite rapidly. I've asked a number of times how you refer to the phenomena of what most of us call "Sunrise" and "Sunset." There must be a reason that you don't respond to that.

You choose to spend much of your time here tap dancing and engaging in Vaudevillian banter.

Hi Mac,

I have not build those monsters but examining the picture, what it looks
like:
The six towers in circle seem to be support for the reflection screens, with
wires stretched between them from top to bottom.
In the middle of each section and on the front of the screens is the tower
with sets of two broadband arrays, which should allow some vertical beam
steering, like a stack of two antennas. So six direction and some vertical
beam steering with great F/B thanks to reflector screens.
On the right there seems to be the classic curtain array with reflectors.

Most of the guys on this group know everything about antennas, lossless
lines, just don't have much in their backyards. :-)

Dear Yuri:

Indeed. See my original posting for a discussion of a circular, curtain array.

Your idea of some vertical beam steering is interesting. That would require adding or subtracting phase to one of the two sections. The picture seems not to show means to perform this bifurcation. The middle doublet has a parallel transmission line going from its middle both upward and downward. Of course, a switching means could be hidden by the mast.

What continues to puzzle me is the use of the two groups of seven doublets that seem to be connected by a mesh butterfly. It may well be that those groups of seven serve the same function as conventional, fat-dipoles in front of a reflector screen.

Unfortunately, my dedicated computer used for modeling died. It had an Intel board that had been stuffed with defective capacitors and only lasted four years. Its replacement (P4 3.2 GHz + 3 GB of memory) has yet to be brought up to speed (something is holding down its performance) - waiting for son's help. In short, I have yet to model the group of seven + butterfly.

Thanks, 73 Mac N8TT

>
> Can not happen after cutting the branches.

The inclusion of circulators in the example
ensures that it is a distributed network example.
Cutting the branches is not a valid action in
distributed network examples because technically
it is a zero current "point" and not a zero current
"branch", i.e. the current is not zero throughout
the entire branch. See below.

Sorry, the lumped circuit model is known to fail for
distributed network problems. That's probably why
the distributed network model still survives today
but has been discarded and forgotten by many in the
rather strange rush to use a shortcut method at all costs.

> Or are you disuputing the validity of cutting branches
> with zero current?

Of course, it is obviously invalid in distributed
network problems. We can add 1/2WL of lossless
transmission line to the example to see why it is
invalid.
1/2WL 50 ohm
SGCL1---1---2--+--lossless line--+--2---1---SGCL2
\ / \ /
3 3
| |
R1 R2

Your zero current "branch" is now 1/2WL long and in
the center of that zero current "branch", the current
is at a maximum value of 0.4 amps for 50 ohm signal
generator voltages of 10 volts as in your original example.

How can the current in the middle of the line be 0.4 amps
when the current at both points '+' is zero? Does that
0.4 amps survive a cut at point '+'?

There are no reflections anywhere in the system. Since
the voltages are equal for the signal generators, we
can only conclude that 0.2 amps of traveling wave current
is flowing from SGCL1 to R2 and that 0.2 amps of traveling
wave current is flowing from SGCL2 to R1. The two current
nodes at the '+' points do NOT indicate that zero current
is flowing in the 1/2WL line. They only indicate that the
two traveling wave currents are equal in amplitude and
opposite in phase at the '+' points. Any cut that disrupts
the flow of those traveling wave currents is invalid.

Oh, I know how to integrate P(t). But I don't
comprehend the utility of the following:

The instantaneous value of voltage is 10 volts.
The instantaneous value of current is 1 amp.
The voltage and current are in phase.

The instantaneous power is 10 joules per 0 sec?

Of course, the sun's rotation and movement through
space have nothing to do with the sun rising, traveling
across the sky, and then setting.

> I've asked a number of times how you refer to the

I have responded four or five times now. If you are
too dense to get it this time, I will probably not reply
again. The sun does NOT "rise", does NOT travel across
the sky, and does NOT "set".

I think we are in sync here, but something is missing. When I think of a traveling sine wave, it must have a beginning as a point of beginning discussion. I pick a point which is the zero voltage point between wave halves. It follows that the maximum voltage point will be 90 degrees later. I think you are doing the same thing, but maybe not.

Next I imagine the whole wave moving down the transmission line as an intact physical object, with the peak always 90 degrees behind the leading edge. In our example 1/2 wave line, the leading edge would reach the open end 180 degrees in time after entering the example. We can see then, that the current peak will be at the center of the transmission line when the leading edge reaches the end.

Again, we seem to be in complete agreement except for the statement "In
those situations, infinite currents or voltages occur during runup".
For many years I thought that "initial current into a transmission line
at startup" would be very high, limited only by the inductive
characteristics of the line. With this understanding, I thought that
voltage would lead current at runup. It was not until I saw the formula
Zo = 1/cC that I realized that a transmission line presents a true
resistive load at startup. Current and voltage are always in phase at
startup.

If we agree that voltage and current are always in phase in the
traveling wave, then we should find that in our example, the system
comes to complete stability after one whole wave (two half cycles) is
applied to the system.

No, because you would find two waves of equal voltage and current
traveling in opposite directions, always arriving at exactly out of
phase, at the source.

Now the question here is "Do the waves bounce off one another?" which
would result in a doubling of observed voltage, or "Do the wave pass
through one another?" which would allow a condition of energy entering
the system equal to energy leaving the system.

No, because a *constant power source* is pumping joules/second
into the system no matter what voltage or current it requires
to move those joules/second into the system. It's like the
power source in "Forbidden Planet".

> Now the question here is "Do the waves bounce off one another?"

Waves do NOT "bounce" off one another. At a physical
impedance discontinuity, the component waves can
superpose in such a way as to redistribute their energy
contents in a different direction. (Redistribution of energy
in a different direction in a transmission line implies
reflections.) In the absence of a physical impedance
discontinuity, waves just pass through each other.

There is a third possibility. The interaction of the two waves can
establish a very high resistance, so high that no current flows-zero.

Does this place us at a logical impasse, with current reversing and
voltage doubling at in one argument (at the open end), but not doubling
at the source end? No, the voltage will double at the source end when
stability is reached after one full cycle (in the 1/2 wave example).

Logically then, we must recognize that our source voltage WILL NOT
remain constant following the arrival of the reflected wave. Certainly
this is what we find when we retune our transmitters after changing
frequency.

What would be the logic of insisting that the input voltage be held
constant to the 1/2 wave example after it is shown that the reflected
wave must interact with the incoming wave give a very high impedance at

the source?

You certainly have. Each of the times I've asked the questions of what you call Sunrise and Sunset, you've not provided an answer.

> If you are
> too dense to get it this time, I will probably not reply
> again.

I'm not at all dense, Cecil, as you know from previous exchanges through the years. I've asked questions. What I get from you in response, does not contain answers. If you choose not to answer, just say so. A threat not to reply isn't really much of a threat.

> The sun does NOT "rise", does NOT travel across
> the sky, and does NOT "set".

Let me ask you once again: If you awaken before dawn and observe the sun when it first becomes visible, what do *you*, Cecil Moore, call the phenomenon you are seeing? Please note that I now say and have previously written that I do not believe that the Sun rises, sets or travels across the sky. I've stated that the terms Sunrise and Sunset are commonly used to describe the Sun's first appearance and last appearance of each day.

Yes, you're describing some of the properties of a sinusoidal traveling wave. I generally describe them mathematically.

They are provided that Z0 is purely resistive. That follows from the simplifying assumption that loss is zero or in the special case of a distortionless line, and it's often a reasonable approximation. But it's generally not strictly true.

But that doesn't have anything to do with my statement, which deals with theoretical cases where neither end of the line has loss. For example, look at a half wavelength short circuited line driven by a voltage source. Everything is fine until the initial traveling wave reaches the end and returns to the source end.
>
> If we agree that voltage and current are always in phase in the

Assuming you're talking about the half wavelength open circuited line driven by a voltage source -- please do the math and show the magnitude

and phase of the initial forward wave, the reflected wave, the wave re-reflected from the source, and so forth for a few cycles, to show that what you say is true. My calculations show it is not. I'd do it, but I find that the effort of showing anything mathematically is pretty much a waste of effort here, since it's generally ignored. It appears that the general reader isn't comfortable with high school level trigonometry and basic complex arithmetic, which is a good explanation of why this is such fertile ground for pseudo-science. But I promise I'll read your mathematical analysis of the transmission line run-up.

The circular array is the Collins Billboard, it covers 9 thru 27MHz, and
is phase steerable thru 360 degrees. The general rumor is that there are
only 2 of them in existance. The one in the picture here in Ceder Rapis
and an identical array belonging to SAC.

The array behind and to the right was a pair of panels for 3 thru 6 Mhz.
They were taken down in 1996.

I am not sure how much longer the circular array will be up and
operational. The antenna farm here at Collins has been significantly
reduced by the addition of new buildings to the campus. We have already
given up a couple of smaller directional arrays and one of the big
log-periodics. :(

There is definitely a problem with that.

But an instantaneous value of 10 joules/sec; that
is useful. With the function describing the
intantaneous values with respect to time, you
can integrate. You can find the total energy
transfered. You can find when it is transferred.
Is it steady? Or does it vary? There is lots
to learn.

You can even learn that when the instantaneous
power at some point is 0 for all instances,
then no energy is transferred. That would be
a useful learning.

OK. I think I should tweak the example just a little to clarify that our source voltage will change when the reflected wave arrives back at the source end. To do this, I suggest that we increase our transmission line to one wavelength long. This so we can see what happens to the source if we pretended that we had not moved it all.

We pick our lead edge at wt-0 and define it to be positive voltage. The next positive leading edge will occur at wt-360. Of course, a half cycle of positive voltage will follow for 180 degrees following points wt-0 and wt-360.

Initiate the wave and let it travel 540 degrees down the transmission line. At this point, the leading edge wt-0 has reflected and has reached a point 180 degrees from the full wave source. This is the point that was originally our source point on the 1/2 wave line. Mathematically, wt-0 is parallel/matched with wt-360, but because the wt-0 has been reflected, the current has been reversed but the voltage has not been changed.

Lets move to wave point wt-1 and wt-361 so that we will have non-zero voltage and current.

vt = vr(wt-1) + vf(wt-361) = 2*.5*sin(1)

where 1v p-p has been originally applied and vf(t) = vr(t) and vt(t) is total voltage at any time point. Notice that the total voltage is now 2vr(t) = 2vf(t). This doubling continues as the wave moves forward, with

vt(t) = vr(wt-2) + vf(wt-362) ..... = 2vf(t) = 2vr(t)

The current is similar except, very important, the current was reversed when reflected from the open end.

it(t) = vf(wt-362) - vr(wt-2) ..... = vf(t) - vr(t) = 0

The effect on the old source point is to make the impedance infinitely high for all ongoing wave forward motion, which is not stopping the

wave, only indicating that power no longer moves past this point.

At time 720 degrees, the reflected wave (wt-0) reaches our revised source point where it matches with wt-720 and begins raising the source impedance, stopping power movement into the system. From this time on, no further power enters the revised system because of the high impedance.

We should notice here that no power leaves the system after this time as well. The high impedance works both ways, for forward and reflected wave. There is no need for additional reflection analysis because both source and full wave systems are stable and self contained after this 720 degree point. The source is effectively "turned off", and the full wave system isolated.

If the source was parallel with a 50 ohm resistor (assuming a 50 ohm transmission line), then the reflected wave would be matched with the resistor and absorbed. Power would be continually moved through the transmission line, giving hot spots on the line at 90 and 270 degree points. We would still see the doubled voltage points at the end (360 degrees) and 180 degree points.

If we move to the shorted transmission line case, the math is identical except that the voltages are reversed but currents add. The result at the source is a low impedance where power can no longer be applied because the voltage is always zero. Could we make current flow through a resistor in parallel to the transmission line at the source in this case? I think not.

So I think.

Thanks for taking time to consider these words. It takes real time to carefully consider the arguments (and to present them).

> There is a third possibility. The interaction of the two waves can
> establish a very high resistance, so high that no current flows-zero.

This is a common confusion of cause and effect. Take a
short-circuit 1/4WL stub for instance. A very high
resistance is established at the mouth of the stub but
that high resistance has zero effect on the forward current
which keeps on flowing into the stub. Without the forward
current flowing uninhibited into the stub, the very high
resistance could not be maintained. In fact, the current
is a maximum at the shorted end of a 1/4WL stub. If you
don't believe it, measure it. Where did that current come
from if current cannot flow into the stub?

The stub impedance is the result of the ratio of voltage to
current. It is a virtual impedance and since it is an effect,
it cannot be the cause of anything. The people who say that
a virtual impedance is the same thing as an impedor have not
read the definitions of those things in the IEEE Dictionary.

You were looking for ideas to improve the gain of a 27MHz signal between a computer mouse and its adapter option o the CPU. I gave a good idea which just might work. You said, forget the radio mouse altogether and just use a long USB cable or buy a new mouse, obviously unacceptable to one who wants to use existing equipment. In fact, you did what you could to discredit my idea. Know what I think "John"? I think you have no original ideas of your own and when you ask others for ideas, you shoot them down, terrified by the thought that someone could actually meet your inane challenges.

I would try vertical polarization or inverted Vee. I know others in this
group may not agree but most man made moise is horizontally polarized (or

was that vertical ;-)) Changing antenna polarizaton may help.

Well, for Christmas I received a Uniden 996T scanner with a:
HUSTLER DCL DISCONE SCANNER ANTENNA BNC CONNECTOR DISCONE MONITOR ANTENA.
40-999 MHZ FREQUENCY RANGE 55" TALL.

I also have a 2m with 5/8W whip magnetically attached to a cookie tray inside the house. It works OK. What I do not have is an SWR meter that operates at 146MHz. When I google discone antennas, I have seen smith chart patterns that show a fairly constant SWR over a large range of frequencies, typically 2:1. However, by the appearance of the antenna it looks like it would transmit at a rather large take-off angle. This antenna is very sturdily comstructed and would easily take the 50W I could put out. Does anyone have any experience in using discone antennas on 2m?

To be quite honest, you got me. As a young man, I had "hippie"
leanings. In all honesty, never out grew 'em ...

However, Marijuana was too slow--avoided opium and its' derivatives like
the plague. Have done barbiturates, alcohol, cross tops, mescaline,
LSD, etc., I can't use my imagination effectively under such
influences--had to give 'em up ... you'll find me much more honest than
clinton ... I inhaled!

Now, I did the above as experiments, maybe I was lucky, I felt I
"learned things", don't do much any more except coffee & cigarettes
(sometimes alcohol--hydrocodone for the broken bone in the neck now and
there will be a day that ends--I count on it.--damn fools want to put a
cadaver bone in my neck!--they ain't foolin' me--that is a dead
mans'/womans' bone!)

I don't like drug addicts, don't find alcoholics much fun either, and
especially if there is a "time element" at play; I do like free
thinkers ...

Sounds to me, you have a problem with my "spirit," more than anything
else, and if you can get that into a "bottle" and "examine" it
closely--I'd be disappointed with myself ... my whole question(s)
is/are, "What have we not examined yet?"; "In detail?"

But then, I came here to argue/debate/explore/learn-about antennas and
everything they touch--and NOT me ... you get this one "freebie" and no
more ...

Regards,
JS

Stored in the 1/4 WL between the short and mouth. No more current
needed once stability is reached.

>

Measured in ohms, virtual, and impedance is not the same as impedor. OK
An effect caused by earlier events. Agreed.

They aren't great, but aren't horrendous either. See the page
at http://njivy.org/node/tim-kyles-discone-antenna-for-802-11b-wi-fi
for both simulated and measured azimuth and elevation plots of
the pattern for a homebrew 802.11 discone. It's a fairly broad
pattern, vertically speaking, and the pattern tilt from the asymmetry
turns out not to matter all that much in many cases.

It'll certainly have less gain towards the horizon than a 5/8-wave on
an infinitely large ground plane. Since you're using a cookie sheet
which is rather smaller than a full wavelength, the discone probably
won't be much worse (the smaller ground plane will perturb the pattern
of your 5/8-wave, most likely). And, a discone mounted outdoors is
almost certainly going to outperform any sort of indoor antenna you
try!

In practice... my city's ARES/RACES group makes extensive use of
discones for pre-sited antenna drops at the city fire stations,
community and senior centers and potential Red Cross shelters, and so
forth. Biggest advantage is their broad SWR bandwidth... we can send
somebody to one of those sites and he can work 2M, 220, or 440 without
having to worry about high-SWR damage to his radio. They work well
enough for our needs.

Another data point... the repeater group I'm a part of uses a discone
for our "remote base" linking radios on 2M and 220. With the antenna
mounted up in the clear on a hospital roof, and about 1 watt of power
out of the link-radio transmitter, we're full-quieting into the input
of a repeater in San Jose around 12 miles away. Again, for our
purposes, the discone is as good as it needs to be.

Just remember to disconnect the discone from your scanner before
transmitting into it :-)

Sorry I'm late, we were away for Xmas.

One thing already suggested is somehow making electrical contact between your body and the antenna terminal so your body acts as a larger effective antenna at the mouse. I wouldn't worry about any impedance mismatch between the RF portion of the mouse and your body, power levels are so low you won't damage anything.

Another thing is making the antenna at the PC bigger, like maybe a full wave loop of #36 magnet wire strung up the walls and across the ceiling and coupled in to the dongle by wrapping it with a few turns of the loop wire. Different orientations of the loop may give you better performance.

Time for some calculus review. Look up differentiation.

Perhaps try googling "in the limit as t approaches 0..."

But at least you now see the utility.

The beauty of the distributed model is that it has
a lot of very, very (say infinitely) small branches.
(Review your calculus, it is much the same). One
can indeed therefore, cut the branch at a point.

If you wish, feel free to view the branch as having,
the width of a point.

> Sorry, the lumped circuit model is known to fail for

Using the distributed network approach, you have added
an infinite number of branches, and now there are two
branches which are appropriate places to make the cut.

Of course the branch in the middle of your line is not
one of them.

> How can the current in the middle of the line be 0.4 amps
> when the current at both points '+' is zero? Does that
> 0.4 amps survive a cut at point '+'?

Absolutely, if the line is lossless. Cut both "+" and the
current in middle of the line still remains.

The point is that in the above example, there are absolutely
no reflections. When you cut the line you cause reflections
where none existed before. It is obviously invalid to completely
change the operation of the circuit in that manner. We could
be sending data from SG1 to R2 and from SG2 to R1. Those data
streams stop when you cut the line.

We both know that is a physical impossibility. Sometimes you
are just forced to accept reality and get on with it.

Nope, I don't. I don't think the concept of instantaneous
power is mentioned at all in "Optics", by Hecht.

My friend went back to using a relay for switching but this got me
interested.

Could a T/R switched be configured as follows for a single frequency setup.
Diode inside the RX
TX conneted to a "T" on the back of the TX thru a 1/4 of coax.
Antenna to the other side of the T

During TX the diode would be forward biased heavily so it appears as a short
across the RX input.

A second idea is to use two antennas on he same tower vertically separated
by 10 ft one for tx and one for rx. Again a diode would be used to short the
rx input during tx.

Jimmie

You've danced and dodged, Cecil.

What do you call the first and last appearances of the Sun's rays each day?

> Incidentally, Webster's says the sun does actually rise. :-)

My local TV meteorologist talks of Sunrise and Sunset. My logging program uses the terms. NASA uses the terms as well.

> where none existed before.

This is what makes the example so fascinating.

Before the cut, there is a distribution of voltage, current
and power on the line. The functions representing these can
be written as

V(x,t)
I(x,t)
P(x,t)

After the cut(s), the voltage, current and power distributions
are exactly the same: V(x,t), I(x,t), P(x,t).

The cuts changed nothing about the conditions in the circuit.

And yet the claim is made that before the cuts there are no
reflections and after the cut there are a bunch. And yet the
conditions in the circuit are EXACTLY the same.
But before:none, after:bunch. But conditions are exactly
the same.

> It is obviously invalid to completely
> change the operation of the circuit in that manner.

Just cutting a branch. Completely legal.

Is the operation of the circuit completely different?
Perhaps it is reasonable to view a virtual open as
producing a reflection. You have to work this out for
yourself. But as you do so, keep front and center the
fact that the voltage, current and power distributions
are identical before and after the cut(s). The before
and after circuits are behaving identically.

If you were merely provided with V(x,t), I(x,t) and
P(x,t) you could not determine whether there were cuts
or not.

> We could
> be sending data from SG1 to R2 and from SG2 to R1. Those data
> streams stop when you cut the line.

The specification of the conditions in the experiment mean
that there can be no data stream. If there were data, the
current would not be always 0.

> are just forced to accept reality and get on with it.

It is completely possible for a lossline line.
It is no different than a connected capacitor and inductor
which will ring for ever given the appropriate initial
conditions.

Ahhh. The difficulty is because you don't "think" that
the concept is mentioned in Hecht. Could that be because
at 5E14 Hz, it is difficult to measure? Try a circuit
analysis or transmission line book. You will have more
luck. There is a good chance that your Ramo and Whinery
mention it. Look near where they derive
Pavg = Vrms * Irms * cos(theta)

With the current always 0, data is not being successfully
transmitted. So with the experiment at hand, life is over.

thanks for the responce, unf i wouldn't be able to put up a quad love
to thou

I actually have a anc4 which practically never seemed to work for
anything in this case i wonder if it might currently my ant and anc4
antenna are together i wonder if i put the anc4 antenna either
further away or perhaps inside the elevator room right near the
equipment (forgot which) that might do it, also my antenna for that
right now is just some old cat 5 i ran to the roof

the idea of a remote might not be to bad since i only need it as a
receiver

> Roy Lewallen, W7EL

That last one will be of particular interest to Cecil.
Its in the Seventh Edition, as well, on page 562.

Of possibly even greater interest to Cecil is the
second entry following 'instantaneous power'...

"instantaneous Poynting vector (P(t,r)) (of an
electromagnetic wave) The vector product of the
instantaneous electric and magnetic field vectors.
The integral of P(t, r) over a surface is the
instantaneous electromagnetic power flow through
the surface."

Come on Cecil! Let's not go around in circles! You know very well how it happens.

On the remote chance that you are serious, I suggest you read CAREFULLY my other postings. If you want even more information, read your own postings from the past.

For my part, I have learned from you and your examples. For better or worse, I feel much more comfortable in my knowledge base and ability to communicate to others. As to the validity of my postings, each reader will need to decide for himself, just as the reader must do for your postings.

No, conditions are not exactly the same. Before the
cut, there were no reflections. After the cut, there
are reflections. Conditions have changed. I'll bet
the change in the natural noise pattern, which exists
in every system, could be detected at the time of
the cut.

If we are talking about things that can happen only in your
mind, why stop with irrelevant ringing assertions? Why not
assert that you can leap tall buildings at a single bound
(in your mind)?

Come to think of it, in a real-world system, the current
is indeed never zero. So if your life depended on it,
would you cut that connection that is keeping you alive?

If you really want to prove your point, you could demand
that the experiment be performed in total darkness with
the two sources turned off.

Hi John, I am also in a deed restricted community and share your pain. Here is what I did for HF - I installed an Inverted L antenna that goes up and over one tree (approx 30' high) and across to a second tree (approx 75'). It is fed at the base with a SG-230 Smartuner. The 'second' half of the antenna is 59 ground mounted radials that go out in straight lines and vary in length between 35' and 75' based on how long I could run them to the property line or other obstruction. The ground radials were stapled to the turf every couple of feet and are now invisible. The only visible part of the antenna is the horizontal wire running between the two trees, but because of the way my lot, house and other trees are arranged in the backyard, the wire is only visible from my back porch!

The antenna works quite well on 160 - 10 meters, and is a big improvement over previous attempts to make something work in the attic because it is outside, well clear of the house everything inside that generates RFI. I got advice on the radial system from Tom, W8JI and Rudy, N6LF and their great web sites listed below.

For 6 and 2 meters sideband/cw I have Par Omniangle 'loop' antennas installed on a pole that I placed in one of the tress in the backyard. The 6 meter antenna is at 20' and the 2 meter one at 15'. All three feedlines are buried where they run from the base of the tress to the house entry point. A little more info plus a couple of pictures are on my web site.

Here's an example using a circulator and load in
a 50 ohm system. Please think about it.

```
SGCL---1---2------------------------------+
\ / | 1/4
3 | WL
| everything is 50 ohms | shorted
R | stub
```

Are there any reflections at point '+'?

If not, how is energy stored in the stub?

If so, what causes those reflections?

4142. Tee-antenna base loading coil?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-28 16:08:57 UTC
From: Navtex-Fan <No@way.invalid>
Message-ID: <mn.e4047d7cd57ee0e4.59994@way.invalid>
Source record: 30608

Hi group,

I've been using a Tee-antenna for Navtex reception on 518 KHz for about 6 months now. Details are here: <http://users.pandora.be/dirk.claessens2/NAVTEX/Tee-antenna.jpg>

I'm very pleased with the results, the thing just works. Almost no local QRM pickup, low noise. I was able to decode really weak Navtex stations in Florida, Puerto Rico, Bahrein. (I'm living near Antwerp, Belgium).

But is this a really optimal antenna setup - given the obvious real estate limitations of my back garden?

When I feed the antenna data into 4NEC2, the following data result:

Z = 241-j1812 Gain = -28.6 dB SWR = 278
I'm assuming that the mismatch is "solved" by the use of the 4:1 UnUn..

If I model a base loading coil of +/- 550 microH , the following results:
Z = 165-j14 Gain = -26.9 dB SWR = 3.3

Question 1: Is installing a base loading coil worth the trouble for receive-only purposes?

Question 2: Should I still use the balun?

Thanks for any advice.

Cheers - Dirk

I am not sufficiently familiar with circulators to respond. My present level of understanding is that they can only be built using ferrite inductors which have an ansiotropic (non-linear) magnetic response. If so, they could not be compared to transmission lines without adding that non-linear factor. Apparently energy is stored in these inductors only if the power is moving in one direction, so it never reaches one branch. I don't understand how a ferrite could do that.

Is there such a thing as a "all transmission line" circulator? If so, where could I find the circuit?

Thanks,

73, Roger, W7WKB

It is good that you agree that the voltage, current
and power distributions are exactly the same, with
and without the cuts. These are the conditions to
which I refer.

I suppose this non-sequitor means that you agree that
an ideal section of transmission line, just like an
ideal inductor and capacitor, will store energy forever
if provided with the appropriate initial conditions,
but do not wish to admit it.

An intriguing thought experiment is to take several
of these sections with stored energy (with the proper
phase relationship) and connect them together. Do
the reflections present at the ends of the short
sections suddenly disappear when the sections
are connected to form a longer line? Are the

reflections now only occurring at the ends of
the longer section?

snip
Please help me out here as I am obviously missing something.
I am referring to a full wave radiator of a dimagnetic material
operating in tank circuit form. During a portion of the cycle
we have eddy currents due to the magnetic field. This magnetic field
is only around for a portion of the time because of the
nature of the material. It is what is happening during this time
that interests me since I theorise that the electric field is
levitating galactic particles. It is during this time I
am trying to understand the status of the inner core.
For instance the skin depth, isn't it changing in thickness?
Is this also producing a void of decaying electrons in the
radiating core etc when there is an absence of a magnetic field
and its absence of a eddy current? I don't want to get into
a standing wave sort of a discussion as the circumstances
appear to be unknown except what other things are at play.
When the magnetic field has dissapated, a short amount of
time before the capacitor discharges and what happens
when the capacitor discharges. I think we can say that
the internal structure of the material changes from
uniform to a random directional structure during this time.

Nope, not necessarily. Most 4:1 designs assume a resistive
load and do not handle reactance very well. A 4:1 device
might make the problem worse.

> If I model a base loading coil of +/- 550 microH , the following results:
> Z = 165-j14 Gain = -26.9 dB SWR = 3.3

As long as your receiver AGC has enough gain to overcome
the loss in the antenna, why worry? Internal receiver noise
is usually negligible compared to atmospheric noise at
518 KHz.

If the circulator is bothering you, forget it and assume the
following lossless conditions:

```
Ifor = 1 amp -->
-----------------------------+
<-- Iref = 1 amp | 1/4
| WL
All Z0 = 50 ohms | shorted
| stub
```

Please think about it and answer the questions above.
The main point to remember is that there is no physical
impedance discontinuity at '+'.

I freely admit that it can happen in your mind (like leaping tall buildings at a single bound). I do not believe it can happen in a real-world situation. But if you can demonstrate lossless transmission lines and lossless inductors on the bench, be my guest and probably win a Nobel Prize in the process.

Reflections are impossible except at physical impedance discontinuities. There are zero reflections at a point in a smooth fixed Z0 section of transmission line. Cut the line and you get 100% reflection. That's why your assertions of "no change" don't make sense. You would have us believe that short circuit to open circuit is "no change"??? If that is true, there's "no change" between a shorted 1/4WL stub and an open 1/4WL stub.

Thanks for the reply Cecil,

Are you suggesting I should not use a unun at all?
I have also experimented with the commercial "magnetic balun" which has
a 9:1 ratio. The only difference I could tell was a _slightly_ lower
noise level.

Cheers - Dirk

Then there would be no antenna. A real antenna has both types of
reactance, capacitive and inductive. In the best antenna, opposite types
of reactance are equal, so balance to zero, only leaving resistances,
radiation and loss types, to impede current into the antenna.

The transmission line, if its Zo matches the antenna, has no standing
wave, but the antenna in many cases has an open circuit at its tip which
generates standing waves aplenty on the antenna itself.

I am not critical of Owen. His posting was the only one I read in the
thread at that spot. Happy New Year to everybody!

Standing waves in devices attached to a transmission lines need not
carry over into the line itself.

A transmission line properly matched to an antenna injects all its
energy into the antenna without reflecting any back towards the
transmitter, thus there are no standing waves on the transmission line..

That is good, for it is unlikely, though with superconductors
one might come close.

> But

More intrigue. This path has been trod before. Begin
with an experiment using ideal elements. Get
uncomfortably close to some truth. Declare the
experiment invalid because it could not happen
in the "real world".

It would be more valuable were you to confront
the demons rather than take the "real world"
escape.

That is why it is so intriguing. The voltage and current conditions have not changed, and yet, before: reflections, after: none.

> That's why your
> assertions of "no change" don't make sense.

Are you claiming that the voltages or currents have changed? Identify a measurable value that has changed and the proof will be yours.

> You would
> have us believe that short circuit to open circuit is

If it does not change the circuit conditions, i.e. voltages or currents.

> If that is true, there's "no change"
> between a shorted 1/4WL stub and an open 1/4WL stub.

Invalid generalization. We were discussing a specific circuit, not any old 1/4WL stub.

4163. 20/40meter 1/4 Dipole?

Newsgroup: rec.radio.amateur.antenna

From: William Longyard <longyard@ix.netcom.com>
Message-ID: <13nb1rg2l4qnl4f@corp.supernews.com>
Source record: 30627

I've got a newbie question, and will appreciate any suggestions.

I've got a very small sailboat that I want to put my Icom706MkIIG into.
I've got the Icom AH-4 tuner, too. What I need is a small inverted "V"
dipole antenna that I can hoist up the mast, which would work with both 20
and 40 meters. I'm thinking that the poles would be about about 8 feet each
on a 1/4 wave.

So...
1. What should the poles actually be, lengthwise?
2. Can I get 20 and 40 out of a single antenna (with tuner)?
3. Do I need to create a copper ground plane in the hull if I use a dipole?
4. Will a 1/4 wave antenna let me use the maximum power of the
radio?(100watts).

Thanks,
Bill

After the initial wave has been propagating 540 degrees along the one wavelength line, it will be back at the input end of the line, not 180 degrees from the source. (I assume that by "full wave source" you mean the source connected to the input end of the line.)

> Lets move to wave point wt-1 and wt-361 so that we will have non-zero
> voltage and current.
>
> vt = vr(wt-1) + vf(wt-361) = 2*.5*sin(1)

I'm sorry, you've lost me already. Where exactly are these "wave points"? By "wave point wt-1" do you mean 1 physical degree down the line from the source, or 1 degree from the leading edge of the intial wave? As it turns out, those two points would be the same after 540 degrees of propagation. But "wt-361" would be one degree beyond the end of the line by the first interpretation, or 1 degree short of the end of the line by the other. What's the significance of the sum of the voltages at these two different points?

I'm increasingly lost from here. . .

Here's my analysis of what happens after the initial step is applied, using your 360 degree line and notation I'm more familiar with:

If the source is sin(wt) (I've normalized to a peak voltage of 1 volt for simplicity) and we turn it on at t = 0, a sine wave propagates down

the line, described by the function

vf(t, x) = sin(wt - x)

At time t = 2*pi/w (one period after t = 0), it arrives at the far end. Just before the wave reaches the far end, we have:

vf(t, x) = sin(wt - x) evaluated at t = 2*pi/w, = sin(-x) = -sin(x)

at any point x, in degrees, along the line. This is also the total voltage since there's no reflection yet.

Then the forward wave reaches the far end. The reflection coefficient of an open circuit is +1, so the reflected voltage wave has the same magnitude as the forward wave. It arrives at the source at t = 4*pi/w (two periods after t = 0), where it's in phase with the forward wave. The reverse wave (for the special case of a line an integral number of half wavelengths long) is:

vr(t, x) = sin(wt + x)

So at any point x (in degrees) along the line,

v(t, x) = vf(t, x) + vr(t, x) = sin(wt - x) + sin(wt + x)

Using a trig identity,

v(t, x) = 2 * cos(x) * sin(wt)

Notice that a standing wave pattern has been formed -- the cos(x) term describes the envelope of the voltage sine wave as a function of position along the line. But notice that the peak amplitude of the total voltage sine wave is 2 rather than 1 volt, except that it's now modulated by the cos(x) position function. Also note that the time function sin(wt) has no x term, which means that the voltage changes all along the line at the same time.

At the moment the returning wave arrives at the source (t = 4*pi/w), sin(wt) = 0, so

v(x) = 0

So the returning wave arrives at the source at the very moment that the voltage is zero everywhere along the line. (For those interested in energy, this means that the line's energy is stored entirely in the magnetic field, or the equivalent line inductance, at this instant.)

Let's follow the returning wave as it hits the input end and re-reflects. The reflection coefficient at the source is -1 due to the zero-impedance ideal voltage source, so the re-reflected wave is

vf2(t, x) = -sin(wt - x)

and the total voltage anywhere along the transmission line just before the re-reflection reaches the far end is vf(t, x) + vr(t, x) + vf2(t, x) = sin(wt - x) + sin(wt + x) - sin(wt - x) = sin(wt + x). Now this is

interesting. When the second forward wave vf2 is added into the total, the standing wave disappears and the total voltage is just a plain sine wave with peak amplitude of 1. It's identical, in fact, to the original forward voltage wave except reversed in phase.

And what happens when vf2 reaches the far end and reflects? Well,

vr2 = -sin(wt + x)

So just before it reaches the input end of the line, the total is now

vf + vr + vf2 + vr2 = sin(wt - x) + sin(wt + x) - sin(wt - x) - sin(wt + x) = 0

For the interval t = 6*pi/w to t = 8*pi/w, the total voltage on the line is zero at all points along the line which the second reflected wave has reached! Further analysis shows that the line continues to alternate among:

v(t, x) = sin(wt - x) [vf only] [Eq. 1]
v(t, x) = 2 * cos(x) * sin(wt) [vf + vr] [Eq. 2]
v(t, x) = sin(wt + x) [vf + vr + vf2] [Eq. 3]
v(t, x) = 0 [vf + vr + vf2 + vr2] [Eq. 4]

How about the value at the input end (x = 0) at various times?

When we had only the first forward wave, it was sin(wt). When we had the original forward wave, the reflected wave, and the new forward wave, it was also sin(wt). And as it turns out, it stays at sin(wt) at all times as each wave returns and re-reflects. I was incorrect earlier in saying that this example resulted in infinite currents. It doesn't, but a shorted line, or open quarter wave line for example, would, when driven by a perfect voltage source.

Just looking at the source makes it appear that we've reached equilibrium. But we haven't. The total voltage along the line went from a flat forward wave of peak amplitude of 1 to a standing wave distribution with a peak amplitude of 2 when the reflection returned to a flat distribution with peak amplitude of 1 when the first re-reflection hit, then to zero when it returned. Maybe we'd better take a look at what's happening at the far end of the line.

The voltage at the far end is of course zero from t = 0 to t = 2*pi/w, when the initial wave reaches it. It will then become 2 * sin(wt), or twice the source voltage where it will stay until the first re-reflected wave (vf2) reaches it. The re-reflected forward wave vf2 will also reflect off the end, making the total at the end:

vf + vr + vf2 + vr2 = sin(wt) + sin(wt) - sin(wt) - sin(wt) = 0

The voltage at the far end of the line will drop to zero and stay there for the next round trip time of 4*pi/w! Then it will jump back to 2 * sin(wt) for another period, then to zero, etc.

In real transmission line problems, some loss will always be present, so reflections will become less and less over time, allowing the system to reach an equilibrium state known as steady state. Our system doesn't because it has no loss. The problem is analogous to exciting a resonant circuit having infinite Q, with a lossless source. It turns out that adding any non-zero series resistance at the source end, no matter how small, will allow the system to converge to steady state. But not with zero loss.

I set up a simple SPICE model to illustrate the line behavior I've just described. I made the line five wavelengths long instead of one, to make the display less confusing. The frequency is one Hz and the time to go from one end to the other is five seconds. The perfect voltage source at the input is sin(wt) (one volt peak).
http://eznec.com/images/TL_1_sec.gif is the total voltage at a point one wavelength (one second) from the input end.
http://eznec.com/images/TL_5_sec.gif is the total voltage at the far end of the line (five wavelengths, or five seconds from the input end).

First look at TL_1_sec.gif. During the time t = 0 to t = 1 sec., the initial forward wave hasn't arrived at the one-wavelength sample point. Then from t = 2 to t = 9, only the forward wave is present as in Eq. 1. At t = 9 sec. the first reflected wave arrives, resulting in a total voltage amplitude of 2 volts peak as predicted by Eq. 2. The re-reflected wave arrives at t = 11 sec., at which time the amplitude drops back to 1 volt peak as per Eq. 3. And at t = 19 seconds, vr2 arrives, dropping the voltage to 0 as predicted by Eq. 4. The pattern then repeats, forever.

TL_5_sec.gif shows the total voltage at the open end of the line, alternating between a 2 volt peak sine wave and zero as predicted.

A nearly identical analysis can be done for the line current.

Let me say once again that the introduction of any series source resistance at all at the input will result in convergence rather than the oscillating behavior shown here, so a steady state analysis of the zero resistance case can be done as a limit as the source resistance approaches zero. But any analysis of the start up conditions on the zero source resistance line should produce the same results derived here mathematically and confirmed by time domain modeling.

4166. Tin Coated Copper Strand Inferior for Wire HF Ant?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-29 00:30:14 UTC
From: Denno <powerwashguy@aol.com>
Message-ID: <8e5720c8-7cca-4c2b-bdae-1e65ebe7a167@f3g2000hsg.googlegroups.com>
Source record: 30629

Hi. I have spool of #12 industrial grade tin coated copper strand wire that I had planned on building a 40 meter vertical loop with. While scouring the web, I came across a white paper on wire, tubing and RF compatibility, and it said that tin-coated copper was "somewhat inferior", but silver coated or pure copper strand were fine for antenna use. Contrary to this, I have read in this Newsgroup that tin or silver coating is a must-have for good RF radiation.

Any views on tin coated copper strand?

Also, where do you all find Copperweld? It sounds ideal, but I haven't been able to find it anywhere.

Thanks!

Oh, boy, the thought of Cecil doing his "proofs" without using lossless lines, pure resistances, inductances, or capacitances, lossless antenna conductors, or any other non-real-world components is enough to tempt me to de-plonk him just to watch the show. But I'm afraid it'll just add more DOO (Degrees Of Obfuscation) to his already formidable toolbox of obscuring and misdirecting techniques. Oh well.

Ohhh gawd, it that a "loaded" question?

I would use it, the lead/tin darkens (oxidizes) with age, so does copper
and most other metals, gold would be nice--too expensive, stainless
would be nice--but then the ohmic losses, use it! ...

End of story...

It won't be the last antenna you construct, build it and learn!

Warm regards,
JS

You don't need a ground plane for a dipole, but for a boat, I would look at
shortened verticals. What do you mean by "pole"?

When a thought experiment deviates far enough from
reality to become impossible, it is necessary to
recognize that one has crossed the line between
reality and mental masturbation. Would you like to
debate how many angels can dance on the head of
a pin?

> It would be more valuable were you to confront
> the demons rather than take the "real world"
> escape.

I have confronted the supernatural and don't believe
in it. Your mileage may vary.

> That is why it is so intriguing. The voltage and current
> conditions have not changed, and yet, before: reflections,
> after: none.

So changes have indeed occurred. A video signal is
a very good one to use to actually see the changes.
If you want to sweep the technical facts under the
rug, now is the time to remind me that a video signal
is not steady state.

> Are you claiming that the voltages or currents
> have changed?

Of course not. I am claiming that reflections have
changed and you seem to agree.

If ignorance is really your goal, why not drop the
experiment in the deepest part of the Pacific Ocean
where nobody can know anything about it?

I agree with JS, just put it up and make contacts.
Best stuff around, of course not, but if you already have it the price is right.

Have been told by I don't know how many people that twisted steel wire is no good.
Our local phone co-op lays it out across the fields when the ground is frozen, hence "field wire", until spring when they can trench the "good stuff" in.
Come spring they roll it up, a mile at a time, and chuck it in the dump.
This stuff is plastic coated, does not break down in UV.
You can just about use it to pull a car out of the ditch it is so strong.
It is a real bugger to wrap or solder, needless to say.
If you put an antenna analyzer on it, get the length right it makes a dandy antenna however.
Even the ice and snow of northeast Montana have not managed to bring them down in over 8 years.
Coated all connections with Liquid Electricians Tape, they still look like new.

Best antenna around, not a chance, BUT, I have yet to have to repair one I have put up, that says a lot for this part of the country.

That's what I was hoping. Actually, I have a few other dipoles out
there with similar stuff and they've been fine. Some antennas are for
other folks so I want to be sure it doesn't turn into a disaster.

I know from experience that tin-coated copper strand is used in the
marine industry because the tin makes the copper much more corrosion
resistant.

As for Copperweld, anyone ever use it?

Not sure what you meant by "loaded question". :-) But I don't visit
the NG's very often.

Thanks,
Denno

Tin plated wire has higher resistivity than solid copper wire. However, in nearly all common antenna applications, the loss of even tin plated wire is insignificant. So it's just fine to use. Likewise, stranded vs. solid wire. Any of the above are just fine.

As for Copperweld, I googled "copperweld" and immediately found that Davis RF carries it. I'm sure that you'd find several other dealers if you'll invest just a couple of minutes looking through search engine results.

I am a "hobbyist", perhaps like yourself ...

Some might think the oxidization of the tin, copper, etc. may result in increased losses (and yes, I have heard this argued--I can only guess) --indeed, logic itself suggests this. I don't know. I have not even attempted to measure it. And, I lack the ability to measure such and my "experiments" take me another avenue ... from use of "oxidized antennas", I don't think it amounts to a significant reduction in "perceived and/or real performance."

Contacts are important ... I would doubt the antenna you propose would be without them ...

Warm regards,
JS

Source record: 30644

A followup:

If we have a transmission line which is an integral number of half wavelengths long, open circuited at the far end, and driven by a perfect voltage source of Vs*sin(wt) in series with *any* non-zero resistance:

The amplitude of the wave reflected from the source will decrease each time, resulting in convergence at the following steady state conditions:

vf(t, x) = (Vs/2) * sin(wt - x)
vr(t, x) = (Vs/2) * sin(wt + x)

Where x is the position from the source in electrical degrees or radians, and vf and vr are the totals of all forward and reverse traveling waves respectively.

The total voltage along the line at any time and position is:

v(t, x) = vf(t, x) + vr(t, x) = Vs * sin(wt) * cos(x)

This clearly shows that the total voltage at any point along the line is sinusoidal and in phase at all points. The "standing wave" is the description of the way the peak amplitude of the sine time function differs with position x.

So the amplitude of the voltage at both ends of the line (where |cos(x)| = 1) will equal the source voltage. The number of reflections (length of time) it will take for the system to converge to within any specified closeness of the steady state depends on the amount of source resistance. If the source resistance is the same as the line Z0, convergence is reached in a single round trip. The time increases as the source resistance gets greater or less than this value. If the source resistance in zero or infinite, convergence to this steady state will never be reached, as shown in the earlier posting.

You've got that right. And nor is it the experiment
under discussion.

> > Are you claiming that the voltages or currents
> > have changed?
>
> Of course not.

So whether the line is cut or not, the same voltage,
current and power distribution exist.

But when the line is cut, it is clear that no
energy is moving between the separate sections.

When the lines are joined, the voltage, current and
power distributions on the line remain the same.
Therefore, no energy is being transferred between
the now joined sections.
QED

With or without reflections, no energy crosses
the points on the line with zero current.

...Keith

Copperweld, or "copper clad steel" antenna wire should not be hard to find. http://www.radioworks.com carries some good coperweld. Belden makes a #14 stranded (7) coppeweld antenna wire, available at http://www.aesham.com , amongst other places.

Personally, I'd use the nice stuff you already have. Good luck.

"Please help me out here as I am obviously missing something.
I am referring to a full wave radiator of a dimagnetic material
operating in tank circuit form. During a portion of the cycle
we have eddy currents due to the magnetic field. This magnetic field
is only around for a portion of the time because of the
nature of the material. It is what is happening during this time
that interests me since I theorise that the electric field is
levitating galactic particles. It is during this time I
am trying to understand the status of the inner core.
For instance the skin depth, isn't it changing in thickness?
Is this also producing a void of decaying electrons in the
radiating core etc when there is an absence of a magnetic field
and its absence of a eddy current? I don't want to get into
a standing wave sort of a discussion as the circumstances
appear to be unknown except what other things are at play.
When the magnetic field has dissapated, a short amount of
time before the capacitor discharges and what happens
when the capacitor discharges. I think we can say that
the internal structure of the material changes from
uniform to a random directional structure during this time."

My comments:

Re: "During a portion of the cycle
we have eddy currents due to the magnetic field. This magnetic field
is only around for a portion of the time because of the
nature of the material."

Correct, there is an eddy (or foucault) current set up due to the magnetic field originating from the time varying current from the generator. If the diagmetic material were water, yes the magnetic field would be 'significant' for only a small portion of the time, if ever, in a moderate time varying magnetic field. For strong static magnetic fields, we have seen that significant eddy curents are set up at the molecular level in water droplets even to the extent that it can levitate against it gravitational field. I assume we are not talking about such strong (static) field here; we are talking about a moderate time varying electromganetic field genrated by a tank circuit.

Re: "During a portion of the cycle
we have eddy currents due to the magnetic field. This magnetic field
is only around for a portion of the time because of the
nature of the material."

Well, depending on the nature of the diamagnetic material, it may either be significant or insignificant. Cu is diagmagetic and in that case the magnetic field always exists in a significant manner to counter the applied magnetic field. The key here is, what is the nature of the diamagnetic material?

Re: "It is what is happening during this time
that interests me since I theorise that the electric field is
levitating galactic particles. It is during this time I
am trying to understand the status of the inner core."

Mu-mesons (cosmic rays) are an example of galactic particles. They are traveling at 0.9c (almost the speed of light) and have the mass of several electrons. Do you think the e-field of the typical antenna could have a significant effect on them considering their large momentum? There will always be some effect I am sure but I'm not so sure it could extend to stopping such particles and slowing them down so they could be in the vicinity of the antenna to experience levitation. I am not sure if there are slower galactic particles or if that is what you are considering in your model. I know there are several types consisting of electrons, protons, neutrons protons etc.. but I would think they must be moving at high speed with a lot of momentum.

Re: "For instance the skin depth, isn't it changing in thickness?
Is this also producing a void of decaying electrons in the
radiating core etc when there is an absence of a magnetic field
and its absence of a eddy current?"

The skin depth does not vary if the frequency remains constant. However, the current density (for example at skin depth) varies in accordance with the signal from the generator from max Js to zero. Wiki will give you the formula for skin depth of a sinusoid and you can see the factors that cause it to vary; resistivity, frequency and magnetic permeability. Yes, at times when the magnetic field is absent (zero cross) I am certain something could be happening at the atomic level of the material in question.

Re: "When the magnetic field has dissapated, a short amount of
time before the capacitor discharges and what happens
when the capacitor discharges. I think we can say that
the internal structure of the material changes from
uniform to a random directional structure during this time."

If you are talking about a parallel L-C tank circuit antenna, I suspect you are correct. Again, I believe this would be at the zero cross points. Yes, at the atomic level the structure must be reacting to the fields imposed previously.

But then again, if we have a coaxial circuit of infinite length, to where any frequency can be expressed in a wavelength, or wavelengths, blah, blah, blah ...

And, if those faeries could just spin straw into gold ... we'd all be rich ...

Some arguments take me in the "general direction" I wish to go, some don't ... you will excuse me ... I am sure ...

On second thought, there are plenty of galactic particles which are
relatively slow moving such as those generated by solar storms and suspend
in the ionosphere after being "grabbed" by the Earth's magnetic field.
Surely some of those particles can drift to the earth's surface influenced
by the relatively weak gravitational forces of the earth. I do not know too
much about the physics involved in galactic particles.

Thanks so much for the info and opinions.

I should have mentioned I am looking for a national supplier of this wire that just may have a branch near where I live. Mail order for something that can get pretty heavy and expensive to ship is something I try to avoid. Shipping costs have skyrocketed along with the price of copper! I try to keep my posts brief; otherwise they seldom are read. I wasn't aware that Belden made this type of copper clad wire. That gives me another avenue to investigate. Thanks.

And, yes, I did use google to search for a local supplier. I found all the mail order places. It amazes me how in so many forums there is some ass lurking in the corner to make a pointed remark towards someone they don't even know. Sheesh!

You know, I just went to the metal scapers and had a "look about", came up with some interesting copper "pipe" 2+ inches, brass pipe and fittings, very HEAVY wire, etc. 5+ bucks a pound for copper!

You just never know, do you ... the coaxial tank for the 2 meter band I am planning will be great, and of course, I am going to attempt coupling "to" that "magical" standing wave ... thanks Cecil!, without 'yas, I'd be bored!

Will have more to say once I "have seen" what this can tell me ...

Regards,
JS

Unless less you are on the baby version of the Queen Mary, I
sort of doubt you have room for full sized 1/2 wave dipoles on
that boat. Maybe 20m... I doubt 40. A full size dipole for 40m
is appx 65 feet long total length. Or about 32 ft per leg, or "pole"
if that is what you mean by pole.
Half that size for 20m.
You might be better off with a vertical. IE: feed your mast as
a vertical, or maybe other ideas could be used. Any dipoles used
may have to be loaded to fit on a very small sailboat.

Sorry that I was not clear at the beginning. I am proposing that we change the experiment to increase the transmission line length from 1/2 wavelength long (180 degrees), to one wavelength long (360 degrees). On the longer line, the initial point on the wave (wt-0) will travel 720 degrees before it returns to the source. Making that assumption, I think my description is correct.

One degree from the leading edge.

As it turns out, those two points would be the same after 540
> degrees of propagation. But "wt-361" would be one degree beyond the end

Good point. I should have respecified 541 degrees of propagation time.
My goal was to look at the voltage at a single point because of the
presence of two parts of the wave at the same place and time.

"x" is referenced from the leading edge of the wave. At time 2pi, a
complete rotation has occurred and the wave front traveled to the open
circuit point. Understood.

> half wavelengths long) is:

As your argument is developed below, you begin using positive x. What
is the zero point it is referenced to? I will assume that it is leading
edge of original reference wave.

Sin(+x) represents a different polarity from the -x reference we were
using prior to this. I will remember this as I move through the
argument.

No, v(t, x) = 0 We need to remember we are carrying two variables here,
like always keeping track of apples and oranges in the same equation.

You begin the following argument using a reflection coefficient of -1,
which reverses the polarity of the wave. Am I to understand that your
model treats the input as a short circuit for the reflected wave? Maybe
I am missing an important point.

In my model, the source voltage must change when the returning wave hits
the input end.

> Let's follow the returning wave as it hits the input end and
> re-reflects. The reflection coefficient at the source is -1 due to the

> vf2(t, x) = -sin(wt - x)

Earlier, we defined the forward wave as vf(t, x) = sin(wt - x), so it is
logical to define vf2(t, x) = sin(wt-x). I do not see the logic in
reversing the voltage polarity with the minus sign.
>
> and the total voltage anywhere along the transmission line just before

> forward voltage wave except reversed in phase.

Wow! This would happen if the re-reflection actually reverses. How
could this occur if we consider that voltage is a collection of positive
or negative particles? We would have a positive reflection meeting with
a positive outgoing wave (or negative meeting negative). The situation
would be the same as at the open circuit end immediately following
initial reversal, or current would simply stop flowing from the source.

I think you would agree that a steady state standing wave would form
immediately upon reflected wave reaching the initiating source if the
wave did not reverse.

I admire the time and effort spent on this analysis Roy. Very well done no matter how history judges the merits of the argument. I think I followed it all, and understood.

The gif's certainly made it clear why you are skeptical of the power of traveling wave analysis.

Could we further discuss the merits of reversing the wave polarity when the reflected wave returns to the source?

At any particular time t=N, what is the variation
in phase for any x between 0 and 90 degrees? If
the variation is zero, how can such a signal be
used to measure delay?

Roy, why must you resort to ad hominem attacks?
Does it mean that you are incapable of winning the
argument on technical merit?

You have even proved yourself and W8JI wrong about
using standing-wave current to "measure" the delay
through a 75m loading coil and don't even seem to
realize it. Here's the equation you posted:

> v(t, x) = 2 * cos(x) * sin(wt)

The equation for I(t, x) would be similar with a
90 degree offset. Please come down from your ivory
tower and explain how that current can be used to
measure delay through a coil.

The point I was making is when imagination is allowed
to run wild in religion or in technical arguments,
anything is possible in the human mind. There simply
has to be a limit oriented to reality.

When a cable is cut at a point where it is known to
be transferring energy in both directions, it is no
longer transferring energy in both directions. That
is reality. No flights of fantasy will change that
technical fact.

It also clearly implies that statement is true for current
as well.

SOMEONE PLEASE PASS THIS CHALLENGE ON TO ROY. HE HAS
DUCKED AND DODGED AND REFUSED TO ANSWER FOR MUCH TOO LONG.
ONE OF HIS PLOYS IS TO SAY HE NEVER SAW THE CHALLENGE
BECAUSE HE HAS PLOINKED ME.

EXACTLY HOW CAN A CURRENT WHICH YOU ADMIT IS IN PHASE AT
ALL POINTS BE USED TO MEASURE THE DELAY THROUGH A 75M
BUGCATCHER LOADING COIL?

It's pretty obvious from experience that Roy would rather
mount an ad hominem attack against me rather than answer
the simple question above.

No, you are the one who believes in the supernatural,
not I. I have confronted those supernatural demons
and decided they don't even exist in reality.

> But when the line is cut, it is clear that no
> energy is moving between the separate sections.

Just as it is clear that before the cut, energy
was moving between the separate sections. It
requires belief in a supernatural to assert that
is not a change.

> When the lines are joined, the voltage, current and
> power distributions on the line remain the same.
> Therefore, no energy is being transferred between
> the now joined sections.
> QED

Change the QED to BS and you will have it right.
When the lines are joined, there is no longer a
physical impedance discontinuity so reflections
are impossible and energy starts flowing again
in both directions.

Believing that reflections can occur where there
exists no physical impedance discontinuity is a
religion, not a science. At that point, I draw
the line - but you are free to have the religion
of your choice. Just please don't try to force
your religion on this technical newsgroup.

> With or without reflections, no energy crosses
> the points on the line with zero current.

Make that no *NET* energy and you will be so
technically correct that I will agree with you.

Not speaking for Roy, but x is usually 0 at the feedpoint
of a 1/2WL dipole, for instance. For any fixed time t=N,
the phase of the standing-wave signal is constant all up
and down the antenna. Please ask Roy how that fixed phase
can possibly be used to measure the phase shift through
a 75m bugcatcher loading coil.

> Wow! This would happen if the re-reflection actually reverses. How

> a positive outgoing wave (or negative meeting negative). The situation
> would be the same as at the open circuit end immediately following
> initial reversal, or current would simply stop flowing from the source.

RF engineering convention in phasor notation: If the wave
reflects from an open circuit, the current reverses phase
by 180 degrees such that If+Ir=0. The voltage does not
reverse phase so Vf+Vr=2Vf=2Vr.

If the wave reflects from a short circuit, the voltage reverses
phase by 180 degrees such that Vf+Vr=0. The current does not
reverse phase so If+Ir=2If=2Ir.

Incidentally, this is a different convention from the field
of optics.

> I think you would agree that a steady state standing wave would form
> immediately upon reflected wave reaching the initiating source if the
> wave did not reverse.

This is a tricky subject covered by many discussions among
experts. My take is that since the impedance "seen" by the
reflections is usually unknown (possibly even unknowable) the
discussion is a moot point. The convention is that if reflected
energy enters the source, it was, by definition, never generated
in the first place. All that is important at the output of a
source is the *NET* power output. Energy flow back into the
source is, by definition, completely ignored.

> The gif's certainly made it clear why you are skeptical of the power of
> traveling wave analysis.

The Poynting vector yields the power density of any EM traveling wave. The power density equations from the field of optics are just as valid for RF waves as they are for light waves. If one wants to understand the redistribution of energy, one will need to understand constructive and destructive interference during superposition. Roy is on record as not caring where the energy goes.

> Please think about it and answer the questions above.
> The main point to remember is that there is no physical
> impedance discontinuity at '+'.

OK. Let's begin by recognizing that this circuit is identical to a
straight transmission line. The purpose of identifying the stub is to
clearly locate the point 1/4 wavelength from the end of the line. The
line is shorted at the end.

We further assume that the peak current is 1 amp.

Are there reflections at point "+"? Traveling waves going in opposite
directions must pass here, therefore they must either pass through one
another, or reflect off one another.

Is it important to decide this issue? Yes, if it will affect the answer
to questions such as what is the voltage or current at this point.

Will it affect the answers? No. Under the conditions described, the
waves passing in opposite directions will have equal voltages and
opposite currents. If they pass through one another, the voltages will
add, but the currents will subtract. If they reflect, the voltage of
each component (Vf and Vr) will add on itself, and the individual
currents will reverse on themselves and therefore subtract. Either way,
the total voltage will double, and total measured current would be zero.
```

There is no reason to decide the issue.

How is energy stored in the stub? We have defined current as entering an leaving the stub. Current is thought of as movement of charged particles, but not as a concentration of particles. A concentration of charged particles exhibits voltage. Energy is present when EITHER current or voltage are shown to be present. Here, current is defined as one amp so energy must be present some place on the line. The stub is 1/4 wavelength long physically, but it is 1/2 wavelength long electrically, so that if we have energy present in the time-distance shape of a sine wave, we would have an entire 1/2 wave's worth of energy present on the stub at all times. The location of peak voltage (or peak current) will depend upon the time-distance reference used to describe the moving wave. (We would have equal voltage(but opposite polarity) peaks located at the point {+} if we assumed the center of the forward and reflected wave each to located 90 degrees from the shorted end.)

The circuit shows forward current Ifor and reflected current Iref as if each were only one current. When we consider traveling waves, we need to remember that Ifor and Iref can be measured on either of the two wires composing a transmission line. The forward wave exists on both wires, but the sides display opposite polatity and direction of current despite both moving in the same direction. It is best to consider the forward traveling wave as two waves, each carrying half the power, with one wave per wire.

Does this match your own concept of the traveling waves acting at the {+} point Cecil? If not, where do we differ?

73, Roger, W7WKB

Is this the kind of answer you were looking for? The answer could be given mathematically but that might be even more confusing.

Cecil,

That is a rather curious comment. Why do you say the convention is different for optics? There are no commonly used "voltage" or "current" descriptions in optics, so analysis is done using E-fields and H-fields. Otherwise there is no difference in convention between optical and RF.

In any case this reversal or non-reversal is not a "convention". It is the mathematical result that comes out of a proper solution to the boundary value problem. The "convention" exists only if one considers Maxwell equations to be a "convention".

.....
Thankyou for that well thought out posting.
It was rewarding for me as I can now
discount the possibility of current returning
thru the center of the conductor if ever that
argument ever comes up, as well as making the
radiatiation action much more clearer.
In the case of a fractional wave radiator
the energy storage facilities are obviously
smaller and quickly filled leaving the rest
of the time for the resistance to absorb
all transient energy.When the capacitor
actually discharges there is zero magnetic
field since the inductor is storing the
energy and not releasing it to a magnetic
field.With the electrostatic field being
released and without a contrary magnetic
field particles are now completely free
to levitate and attempt move out of the
arbitary gravitational border.
This very sequence of actions gives
credability to NASA's aproach to removing
moon dust from astronauts outer wear by
subjecting them to a electro static charge.
Fortunately the subject of phantom waves
was not involved and the thread comes to a
succesful completion.
You sir, are a very welcome addition to
this newsgroup and hopefully you can
withstand the abuse given which is usually
the sign of the absence of knoweledge.
My very best regards

The Belden copper-clad #14 with 7 strands is Belden PN: 8000 .
You should be able to find local distributers for Belden products most places. Also, I do not think that 100 foot spools of Belden 8000 are big or heavy enough to warant any worry about shipping costs.... we are only talking a pound or two. I ordered a couple hundred feet of this some years ago and don't believe the shipping costs were any concern then.

> used to measure delay?

The equation is a correct equation for describing a standing wave. It is not describing a signal. It is a voltage-time-location(not distance) relationship for a defined situation.

Having measured the voltage at two x points, from the equation I could find the rotational angle of the wave at both points. The difference between the two angles would be the distance of wave travel assuming the standing wave was composed of traveling waves.

I don't think I would call that a measurement of delay, nor of phase. I would call it a measurement of distance traveled on the transmission line.

Try a local welding supply house for copper-coated "wirefeed" welding wire.
I think it's what the antenna supply folks repackage.

No. x is referenced to the input end of the line. This is very important. I'm sorry my statement that it is "any point x, in degrees, along the line" didn't make this clear.

> As your argument is developed below, you begin using positive x. What
> is the zero point it is referenced to? I will assume that it is leading

No, it's the input end of the line.

> Sin(+x) represents a different polarity from the -x reference we were
> using prior to this. I will remember this as I move through the argument.

Sorry, but I don't understand this statement.

> You begin the following argument using a reflection coefficient of -1,
> which reverses the polarity of the wave. Am I to understand that your
> model treats the input as a short circuit for the reflected wave? Maybe
> I am missing an important point.

Yes, that is correct. The impedance of the source (a perfect voltage source) is zero, so the reflection coefficient seen by the reverse traveling wave is -1.

> In my model, the source voltage must change when the returning wave hits
> the input end.

Then we've been using a different model. The one I've been using is the one proposed by "Dave" -- a half wavelength open circuited line driven by a voltage source -- except with your change in line length to one wavelength. You cannot cause the voltage of a perfect voltage source to change.

>> Let's follow the returning wave as it hits the input end and

> reversing the voltage polarity with the minus sign.

The original forward wave is sin(wt - x). The reflected wave is sin(wt + x), where the change in sign of x is a consequence of the reversal of direction. Reflection from the source causes an inversion of the wave polarity because of the -1 reflection coefficient, and another sign change of x due to the reversal of direction, resulting in the equation above.

>> and the total voltage anywhere along the transmission line just before
>> the re-reflection reaches the far end is vf(t, x) + vr(t, x) + vf2(t, x)
>> = sin(wt - x) + sin(wt + x) - sin(wt - x) = sin(wt + x). Now this is

>
> Wow! This would happen if the re-reflection actually reverses. How
> could this occur if we consider that voltage is a collection of positive
> or negative particles?

Well, if it couldn't, then your concept of voltage is flawed. You might re-think it.

> We would have a positive reflection meeting with
> a positive outgoing wave (or negative meeting negative). The situation
> would be the same as at the open circuit end immediately following
> initial reversal, or current would simply stop flowing from the source.

In fact, current does quit flowing from the source. The line is fully charged and there is no load to dissipate any further energy from the source. Any analysis showing continued current from the source is obviously wrong for that reason.

> I think you would agree that a steady state standing wave would form
> immediately upon reflected wave reaching the initiating source if the
> wave did not reverse.

I'm sorry, I don't understand that question.

> I admire the time and effort spent on this analysis Roy. Very well done
> no matter how history judges the merits of the argument. I think I
> followed it all, and understood.

As I've mentioned, there are other valid ways of analyzing such a circuit. At the end of the day, any analysis must produce the correct result. Getting the correct result doesn't prove that the analysis is valid, but failure to get the correct result proves that an analysis is invalid. SPICE uses fundamental rules for analysis, so is a good

authority of what the answer should be, and it shows that my analysis has produced the correct result.

> The gif's certainly made it clear why you are skeptical of the power of
> traveling wave analysis.

The SPICE results are simply a way of verifying that my analysis is correct. The concept of traveling waves of average power has other, serious problems.

> Could we further discuss the merits of reversing the wave polarity when
> the reflected wave returns to the source?

Sure. First please review the concept of reflection coefficient.

The behavior of the returning waves when they reach the source is often not included in transmission line analysis because it plays no part in determining the steady state SWR, impedance, or relationship between voltages and currents at the ends or anywhere else along the line. The only thing it impacts is the way steady state is reached during turn-on, and not the final steady state condition itself, and this isn't generally of interest. (An exception is the contrived and actually impossible case of a completely lossless system such as the one I analyzed, and it's not an exception either if viewed as a limiting case.) As I mentioned in my posting, the steady state result is exactly the same for any non-zero source resistance; the only effect of the resistance is in determining how steady state is reached.

> Maxwell equations to be a "convention".

I'm not seeing Cecil's comments in context, so this might be irrelevant, but there is a convention involved with the direction of reverse-traveling current waves. The common convention used in transmission line analysis is that the positive direction of both forward and reverse current is from the generator toward the load end of the line. The consequences of this is that the current reverses sign -- really meaning only that it reverses direction -- upon reflection from an open circuit (+1 voltage reflection coefficient), and it allows calculation of the total current as the sum of the forward and reflected currents. An equally valid convention is to define the positive direction of both forward and reflected currents to be the direction of travel. If this convention is used, then the current undergoes no change in sign upon reflection. But the total current then equals the forward current minus the reverse current. Either convention will produce correct results, of course, as long as it's carefully and consistently applied.

OOOOps, I retreated to quickly!
In a fractional wave length antenna the
inductance and capacitance vessels are to
small for a full frequency step of applied
current such that the total resistance of
the system is forced to consume the continueing
energy flow. Naturally the cuurent direction
cannot change and go back thru the resister
leaving only the path down the center of the
radiator to get back to the generator.
If this patheresistance is the same as the
external resistance then mathematically it
doesn't change things. However, it is different
in a very small way thus total radiation
efficiency with respect to unit length can
only be a maximum when the radiator is a multiple
of a wave length long
i.e. in equilibrium as in the Gaussian field.
I think that wraps things up for the theorem.
Regards
Art Unwin ...KB9MZ....XG(uk)

In the Marine Radio Biz, we ALWAYS use 7/20 Phosphor/Bronze as LF/MF/HF
Antenna Wire. It doesn't corrode in the Salt Atmosphere, and has real
good Conductivity, when compared to anything else, that would still be
around in a couple of months. Of course now that SAT Phones have arrived,
not much use for LF/MF/HF in the Marine Comm biz.....

In the absence of a real physical impedance discontinuity,
they cannot "reflect off one another". In a constant Z0 transmission
line, reflections can only occur at the ends of the line and only
then at an impedance discontinuity.

> Does this match your own concept of the traveling waves acting at the
> {+} point Cecil? If not, where do we differ?

Where we differ is that you allow traveling waves to "reflect
off one another". There are no laws of physics which allow
that in the absence of a physical impedance discontinuity.
EM waves simply do not bounce off each other.

4237. Small tuned loops

Newsgroup: rec.radio.amateur.antenna
Date: 2007-12-29 19:46:20 UTC
From: Steve <sdaniel13@speakeasy.net>
Message-ID: <a3a7bbcb-e980-41e9-9ec8-e01c23a6bd5e@l6g2000prm.googlegroups.com>
Source record: 30454

I notice that MFJ has a loop tuner (model 936b) that allows you to use varying lengths of wire and varying materials (wire, copper tubing) to make loops resonant on different bands. Has anyone used one of these to tune small to medium sized loops and, if so, what were the results?

I wonder how this item would compare with either the MFJ high q loops (models 1982-1788) or with a wire loop tuned with something like an SGC 320 auto tuner.

I'd appreciate any insights you can share.

Thanks.

Steve

In optics, to the best of my knowledge, there is no separate
reflection coefficient for the E-field and the H-field. If
true, that fact alone implies a different convention from
the field of RF.

> The equation is a correct equation for describing a standing wave.
> It is not describing a signal.

Roy thinks it is describing a signal and so does W8JI.
It's the signal current they both used to "measure" the
delay through a 75m bugcatcher loading coil.

> Having measured the voltage at two x points, from the equation I could
> find the rotational angle of the wave at both points. The difference
> between the two angles would be the distance of wave travel assuming the
> standing wave was composed of traveling waves.

But that's not what Roy did. He measured the difference
in phase between two current measurements in a standing-
wave environment and declared that lack of phase difference
to be the "delay". He did NOT measure amplitude and calculate
backwards to get the delay. That's what I said he should
have done and he ploinked me.

Correction: I meant to refer to the SGC 230 auto tuner, not "320".

Steve

Roy Lewallen wrote:
> In fact, current does quit flowing from the source.

In your example, the only way for the conservation of
energy principle to work, along with the laws of physics
governing EM waves, is for the reflected wave incident
upon the source to be reflected back toward the open
end of the stub. The forward and reflected energy simply
remains in the stub flowing end to end at the speed of
light in the medium. Anything else is impossible.

> As I've mentioned, there are other valid ways of analyzing such a
> circuit. At the end of the day, any analysis must produce the correct
> result.

My analysis produces the correct result but you have rejected
it out of hand. My analysis is the method by which EM light
waves are analyzed.

Thanks Roy, the former is the convention usually used for RF
wave analysis. The latter is the convention usually used for
light wave analysis. They are obviously different conventions.

When the source impedance is the same as Z0 there
is no impedance discontinuity to produce a reflection.

Is the reflected wave reflected even without a
discontinuity?

...Keith

PS. And a circulator is not needed for the source
impedance to match Z0.

Well something causes you to latch up and bail with
"its not real world", though there was no protest
when the initial experiment is specified using
ideal elements.

> > But when the line is cut, it is clear that no

> requires belief in a supernatural to assert that
> is not a change.

But you previously agreed that P(t) = 0 for all t,
and therefore no energy was moving between the sections.
Recall that P(t) = V(t) * I(t) and that at the
point on the line in question, I(t) is zero for all
t, therefore P(t) is zero for all t. So no energy
flow between the sections.

> > When the lines are joined, the voltage, current and

This is the kind of comment that suggests stress,
rather than rational examination.

> When the lines are joined, there is no longer a
> physical impedance discontinuity so reflections

> in both directions.

But as previously discussed, no energy flows. The
the voltage, current and power distributions are
the same, whether the line is cut or joined.

> Believing that reflections can occur where there
> exists no physical impedance discontinuity is a
> religion, not a science.

Red herring. Straw man. I do not recall anyone
making the claim that reflections exist with no
physical impedance discontinuity. (Although you
did raise the possibility in another post).

> At that point, I draw
> the line - but you are free to have the religion

> technically correct that I will agree with you.

Sometimes when writers write NET, they mean time
averaged, but that is not your intent here, is it?

You do mean that P(t) is zero for all t at the
points on the open circuited line where the voltage
or current is always zero. Right?

There is no difference. The H-field is related to the E-field by the properties of the medium. The current is related to the voltage by the properties (Z0) of the medium. It is therefore possible to calculate a single reflection coefficient. It is the same situation at RF as at optical frequencies.

If you are referring to the sign change of the current reflection for open vs. short circuit, then there is still no difference. The formula for the reflection coefficient contain terms that change sign depending on the relative properties of the media. It matters not whether one is dealing with HF or visible light.

Roger: an astute observation. And Cecil thinks he has
the ONLY answer. Allow me to provide an alternative.

Many years ago, when I first encountered this news group
and started really learning about transmission lines, I
found it useful to consider not only sinusoidallly
excited transmission lines, but also pulse excitation.
It sometimes helps remove some of the confusion and
clarify the thinking. So for this example, I will use
pulses.

Consider a 50 ohm transmission line that is 4 seconds
long with a pulse generator at one end and a 50 ohm
resistor at the other.

The pulse generator generates a single 1 second pulse
of 50 volts into the line. Before and after the pulse
its output voltage is 0. While generating the pulse,
1 amp (1 coulomb/s) is being put into the line, so
the generator is providing 50 watts to the line.

After one second the pulse is completely in the line.
The pulse is one second long, contains 1 coulomb of
charge and 50 joules of energy. It is 50 volts with
1 amp: 50 watts.

Let's examine the midpoint (2 second) on the line.
At two seconds the leading edge of the pulse arrives
at the midpoint. The voltage rises to 50 volts and
the current becomes 1 amp. One second later, the
voltage drops back to 0, as does the current. The
charge and the energy have completely passed the
midpoint.

When the pulse reaches the end of the line, 50 joules are dissipated in the terminating resistor.

Notice a key point about this description. It is completely in terms of charge. There is not a single mention of EM waves, travelling or otherwise.

Now we expand the experiment by placing a pulse generator at each end of the line and triggering them to each generate a 50V one second pulse at the same time. So after one second a pulse has completely entered each end of the line and these pulse are racing towards each other at the speed of light (in the line). In another second these pulses will collide at the middle of the line.

What will happen? Recall one of the basics about charge: like charge repel. So it is no surprise that these two pulses of charge bounce off each and head back from where they came. At the center of the line, for one second the voltage is 100 V (50 V from each pulse), while the current is always zero. No charge crossed the mid-point. No energy crossed the mid-point (how could it if the current is always zero (i.e. no charge moves) at the mid-point.

It is a minor extension to have this model deal with sinusoidal excitation.

What happens when these pulses arrive back at the generator? This depends on generator output impedance. If it is 50 ohms (i.e. equal to Z0), then there is no reflection and 1 joule is dissipated in each generator. Other values of impedance result in more complicated behaviour.

So do the travelling waves "reflect" off each other? Save the term "reflect" for those cases where there is an impedance discontinuity and use "bounce" for those cases where no energy is crossing a point and even Cecil may be happy. But bounce it does.

The guy on the other end of the QSO will never be able to tell the difference between your signals coming from your bare copper wire antenna and those coming from your tinned copper wire antenna. Tinned copper wire is much more corrosion-resistant than any form of bare copper wire and tinned stranded wire is mechanically much more durable than any form of solid wire when used as antennas.

http://www.boatus.com/boattech/casey/05.htm

A 40M loop made from your #12 tinned stranded wire should serve you well for a long time so go for it.

My favorite source for all sorts of "ham wires":

http://thewireman.com/index.shtml

The ultimate antenna wire in my view is his #13 'Toughcoated' tinned stranded 'Copperweld' P/N 531

Yes, it is critical. I am sorry that I misunderstood this.

In our example then, "x" will always be positive. How am I to interpret
the meaning of vf(t, x) = sin(wt-x)?
>
>> As your argument is developed below, you begin using positive x.

I understand that the convention for displaying a sin wave is that one
rotation is 2pi radians with positive rotation being counter clockwise
beginning with sin(x) = 0. Sin(90) = 1. Counter clockwise rotation
would indicate the the sin immediately becomes negative,
so sin(-90) = -1.
>

> traveling wave is -1.

The logic of this assumption eludes me. In fact, it seems completely
illogical and counter to the concept of how voltage and current waves
are observed to move on a transmission line.

Maybe my concept of voltage being a concentration of positive (or
negative) charges is leading me astray. If two waves move in opposite
directions, but both of a positive character, at the time of crossing
paths, the voltages add. It happens at the open ends when the direction
reverses. It MUST happen identically when the reflected positive wave
returns to the source (at time 720 degrees in our one wavelength
example) and encounters the next positive wave just leaving the source.

>> In my model, the source voltage must change when the returning wave

Are you assuming that vr is always propagating from the source as if the
source always supplied vf and vr simultaneously? As if vf was supplied
for time = 4pi, and then vr was applied?

Your idea of a 5 wavelength long example was a good one Roy. It may provide a way out of what seems to be a logical impasse (reversal at the voltage source may be uncompromisable).

We could allow our future discussions (if any) to consider an extremely long line, but consider only the 1/2 or 1 wavelength at the end for our discussions. Thus, the source (and source for major disagreement) is far removed from our discussion section. We could then consider the input source as just another node for as long as we wanted.

Traveling waves easily explain standing waves on a 1/2 wavelength section, as you demonstrated. Maybe they can explain or clarify more things if we can get past "hang ups" such as the " -1 reflection at a perfect voltage source".

Keith Dysart wrote:
> When the source impedance is the same as Z0 there
> is no impedance discontinuity to produce a reflection.

Here's a quote from "Fields and Waves ..." by
Ramo and Whinnery: "... significance cannot be
automatically attached to a calculation of power
loss in the internal impedance of the equivalent
circuit."

And from "T-Lines and Networks" by Walter C. Johnson:
"Although the Thevenin equivalent produces the correct
exterior results, its internal power relations may be
quite different from those of the network it replaces.
The power dissipated in the equivalent impedance of the
Thevenin circuit is not the same as the power dissipated
in the resistance of the actual network."

Translation: Do not use a Thevenin source impedance
to try to track power dissipation within the Thevenin
equivalent box - it won't work. Your argument that
there is zero power dissipation in the source resistor
inside the Thevenin equivalent box is bogus.

> Is the reflected wave reflected even without a
> discontinuity?

The incident reflected wave is either reflected by the
source or it isn't. You cannot have it both ways. Since
the internal conditions inside a Thevenin equivalent
circuit are a complete unknown, either choice is
a possibility.

What you will find is that, for a real-world source,
the destructive interference on one side of the source
equals the constructive interference on the other side
of the source. The conservation of energy principle
prohibits having it any other way.

I completely concur with your analysis.

No doubt you have fine tuned the analysis to notice that the current stops (meaning becomes unobservable) at the identical instant that the voltage spike (to double) is observed. You would have noticed that the zone of unmeasurable current spreads equally both ways from the collision point at the velocity of the wave(s). The voltage spike spreads in lock step with the loss of current detection. The maximum width of the loss of current and voltage spike is the width of either of the pulses.

Now did the two pulses reflect, or pass through one another? I have considered the question and can not discern a difference in my analysis either way. IT SEEMS TO MAKE NO DIFFERENCE!

Roy and I are talking about this on other postings. I guess the purest might point out that a 50 ohm generator only has a voltage to current ratio of 50, but we don't know if it also has a resistor to absorb energy. It is like a black box where the only thing we know about it is that when we connect a 50 ohm resistor to it through a 50 ohm transmission line, there are no standing waves.

In this case, a reflected wave could be used like a radar pulse to learn what might be inside the box.

Sorry John you have it wrong..

Yes the recovered audio can be of very high "quality".

The signal however that you "decode" has to be some level higher than that of the noise present in that bandwidth. In this case the "noise" has nothing to do with what you hear, but what is present as a random voltage at the RX input. Eb/No is an expression of that signal vs noise level. If your general noise level is higher (eg from BPL) then your wanted signal also has to be at that level. (or rather slightly higher)

So by itself digital voice won't help in a high noise environment. There may be some facility however to use the structure of a BPL signal though to transmit and receive where there is less interferring energy present, I understand that BPL is a series of "spikes" that you may be able to fit signal in between. I have BTW never looked into this and dont know whether it is viable.

Cheers Bob VK2YQA

If you have time to wait before you work on your antenna
I expect to put an antenna together with #22 tinned solid wire.
I intend to wind my wire on a small diameter plastic tubing
for a sufficient length to slide onto 3/4 of the circumference

leaving the remaining quarter for the wire to stretch to find
a sweet spot. When I have reached required the 3/4 length I will
then continue the winding back to the starting point so that both
feed ponts are close together.It is required that you cut the wire
at the end of the windings so that you can unwind each wire
end one loop and then fasten the ends with a wire nut.
This loosens the turns just enough to make it easier to slide
of the former and onto the hula hoop. Tho I am confident that
a sweet spot will occur with stretching the windings. It
is usefull to add a plate capacitor in series with the feed wire
which allows you to move freely the wide existing bandwidth of the
helical loop of the antenna. The information given will allow
you to procede with building your own if your time is getting short.
If you cannot get sufficient wire length on the former for the
frequency required then by all means run another wire length
over the previous windings before you slide it over the hula hoop.
Hoops were less than $5 at Wallmart the last time I looked and they
have a insert in the tubing that can be removed for the
assembly operation This method of winding gives multiple resonant
points
way closer than you would find using other methods so the addition
of the capacitor if large enough will allow you to cover the other
bands.
If you are smart you can also stretch the windings at will if you
have the need to get closer to alternate frequencies.
As a side issue it is much better if you use solid wire insulated
wire rathe than stranded as this provides much better outward spring
to the loops and some clearance over the hoola hoop during assembly.
The above will give the same radiation as if the wire was stretched
out
but with a minimum of volume used, tho the take of angle rules still
stands with respect to height. Also note that with the radiation
being concentrated at a relative point basis one should not stand
near the hex loop near field for health reasons.
Best regards and good luck.

Cecil, this sounds more like a pronouncement from God than like an
conclusion from observations.

I am not aware of any laws of physics that prevent it either. I don't
see any evidence that it happens in open space, like light bouncing off
light. It might happen on transmission lines however. I just cannot
find any convincing evidence either way. What I have deduced so far
indicates that it makes no difference which happens.

Maybe both things happen (both reflect and pass). This because the EM
field travels very close to the speed of light. It is a little hard to
see how one wave could "see" the other coming. On the other hand, the
charges move slowly, far below the speed of light. It is easy to see
how they might "see or feel" each other coming.

John,
Traps make no sense as they just waste power.
It is so much more efficient to base antenna lengths in multiples
of a wavelength especially when using top band.

Absolutely not.

However, the best data compaction/error control code is patented. Ogg Vorbis is excellent.

You don't need the hardware I pointed out, an old computer with a half-way decent sound card can serve just as well--better, it the quality of the sound card is high. In fact, that is what I use myself. The software can be found with google searches and excellent apps can be found which is freeware.

The only cost you have to incur is cabling/interface, and I am sure most amateurs have the "stuff" in their junk drawers ...

With the right software, the digital packets only need "just clear" the noise floor ...

Art:

Everything which is placed in a transmission line/antenna circuit has to "burn" some amount of power ...

You sound like me, when I had the "back 40+ acres." City dwellers (indeed, myself in my present situation) need one antenna to do it all ... (actually, I got 3 separate stealth antennas doing the job--but you get the idea ...)

I know, you recommend the "magnetic loops/etc.", however, it is all about choice.

Warm regards,
JS

Heck, Brian, I was just going to suggest that you make some
substantional portion of your antennas out of long steel springs. You
could tie a rope to an end and change bands by simply letting out on the
rope and allowing the springs to compress, heh heh.

Therein lies the rub, "John". I'm sure you've listened to what a BPL signal sounds like. If you have a power line spewing that stuff at S9+ running past your place, the only thing you'll be hearing, other than locals running a KW, will be the BPL sigs. Folks on the other side of the continent will likely hear your digital voice signals; you won't likely be able to copy them.

Geesh Dave, someday come up to speed!

You should see the data packets flying about on a healthy internet backbone or BIG wireless net--and yet, all get to the right places--a browser (or, any savvy app) "knows its' own" ... hint, CRC sums--for one thing ...

Actually, a very good recommendation--for some limited applications ...

I have seen just such done, only with phosphor-bronze springs, and of
limited frequency bandwidth ...

True indeed.

> And from "T-Lines and Networks" by Walter C. Johnson:
> "Although the Thevenin equivalent produces the correct
> exterior results, its internal power relations may be
> quite different from those of the network it replaces.
> The power dissipated in the equivalent impedance of the
> Thevenin circuit is not the same as the power dissipated
> in the resistance of the actual network."

Different words, but still true.

> Translation: Do not use a Thevenin source impedance
> to try to track power dissipation within the Thevenin
> equivalent box - it won't work.

No need for translation, though this is not quite what
was said above. Note the words "automatically" in the
first quote and "may be quite different" in the second.
The original authors allow for the possibility that it
might be the same, while your "translation" removes
that possibility.

> Your argument that
> there is zero power dissipation in the source resistor
> inside the Thevenin equivalent box is bogus.

Nowhere has that argument been made.

> > Is the reflected wave reflected even without a
> > discontinuity?
>
> The incident reflected wave is either reflected by the
> source or it isn't. You cannot have it both ways.

It is not I who wants it both ways. For me it is clear
that there is no reflection when the output (source)
impedance is the same as Z0. And when it is not equal
to Z0, there is a reflection.

> Since
> the internal conditions inside a Thevenin equivalent
> circuit are a complete unknown, either choice is
> a possibility.

Not when the output (source) impedance is known. It is
then easy to compute the magnitude of the reflection
using the standard rules for reflection coeficient.

> What you will find is that, for a real-world source,
> the destructive interference on one side of the source
> equals the constructive interference on the other side
> of the source. The conservation of energy principle
> prohibits having it any other way.

Except when the output (source) impedance is equal to
Z0, in which case there is no reflection, and, if I
understand your claim, no interference, destructive
or constructive.

John
As you know from personal experience one can make antenna with
windings
finishing at the top of the radiator, but it must be seen as being
resonant
by virtue of the added resistance. This is exactly why Prof Hately was
unsuccesful with his contraversal small broadcast band antenna
first tested in Egypt, then Australia and then the Isle of Man.
This is also also why that antenna made by that guy in Florida(Hart?)
is not as efficient as he and Hately led themselves to believe.
Remember that our latest antenna inventor from RI also used a single
winding type of antenna in a way similar to a slinky to which you
were refering to, but then you have to ask yourself why these antennas
were not efficient, and why RI and others had to increase the diameter
of the
radiator wire because their designs melted? All of these antennas
problems
can be solved just by adding to the antenna length in a contra wound
fashion back to the antenna base thus negating the need for ground
planes and thicker wire.
This is exactly why the loop antenna that I was talking about
in another thread is to be made out of #22 wire since, unlike
the RI antenna the wire will not melt because of excess heat
Instead this lost energy will now contribute to radiation .
If you refer to the thread of "current travel down the center
of the radiator" in the absence of a radiating surface you
will better understand the relationships to Gauss and static

law. That thread has now come to a satisfactory completion
as far as I am concerned.
As for Cecil's postings,that thread will never come to a
satisfactory conclusion since the moment in time has not
been stipulated. But even if one side or another was
proven correct one must ask themselves as to what advantage
is it with respect to antennas if agreement is finally
arrived at? But then it is well known in psychology circles
that agreement can never come about when one of the
parties are angry or confused which provides for
personal attack
Very best regards

> the meaning of vf(t, x) = sin(wt-x)?

No interpretation necessary. Plug in a time t and distance x from the input end of the line in degrees, and the result is the value of the forward voltage wave at that time and place. For example, if the frequency is 1 MHz, w = 2.828 X 10^6/sec. So 100 ns from the time you connected the source (or 100 ns from the beginning of any source cycle, since the signal is periodic), the value of the forward voltage wave 20 degrees from the input of the cable is sin(2.828 X 10^6 * 100 X 10^-9 radians + 20 degrees) = sin(36.2 degrees) ~ 0.59 volts.
>

> so sin(-90) = -1.

I usually display sine waves on a linear graph of value vs. time, as in the .gif files I referenced. There is no rotation involved. Apparently you're referring to the display of phase angle on a polar graph, but I don't see where you're getting the values you're describing. A phase angle of 90 degrees is at 0 + j1 on the graph, or 90 degrees CCW from the real axis; -90 degrees is 90 degrees CW from the real axis, at 0 - j1.

Consider that it can be derived various ways, agrees with all published information and, as I've demonstrated, can be applied to get the correct answer to a transmission line problem.

> Maybe my concept of voltage being a concentration of positive (or
> negative) charges is leading me astray. If two waves move in opposite
> directions, but both of a positive character, at the time of crossing
> paths, the voltages add.

The from two waves always add, vectorially, no matter what the
direction, value, or polarity, as long as they're in a linear medium.

> It happens at the open ends when the direction
> reverses.

Any time the Z0 of the medium or transmission line changes, a reflection
takes place. The magnitude and angle of the reflected wave compared to
the original wave is known as the reflection coefficient. An open end is
only an extreme case, where the reflection coefficient is +1.

> It MUST happen identically when the reflected positive wave
> returns to the source (at time 720 degrees in our one wavelength
> example) and encounters the next positive wave just leaving the source.

No, for two reasons. One: Contrary to Cecil's theories, one wave doesn't
cause any change in another. Although they vectorially add, each can be
treated completely independently as if the other doesn't exist. If
you'll look carefully at my analysis, I did just that. Two: The input in
the example isn't an open circuit, but exactly the opposite case: it's a
perfect voltage source, which has a zero impedance.

>>> In my model, the source voltage must change when the returning wave
>>> hits the input end.
>>
>> Then we've been using a different model. The one I've been using is
>> the one proposed by "Dave" -- a half wavelength open circuited line

>> source to change.
>
> Are you assuming that vr is always propagating from the source as if the
> source always supplied vf and vr simultaneously? As if vf was supplied
> for time = 4pi, and then vr was applied?

I am assuming that the source provides vf. All other waves result from that.

> Your idea of a 5 wavelength long example was a good one Roy. It may
> provide a way out of what seems to be a logical impasse (reversal at the
> voltage source may be uncompromisable).

The analysis is identical with a one wavelength line, and nearly so with
a half wavelength one. It's just that the various forward and reverse
waves exist independently long enough on the 5 wavelength line that you
can see the effect on the total which each one has.

> We could allow our future discussions (if any) to consider an extremely
> long line, but consider only the 1/2 or 1 wavelength at the end for our
> discussions. Thus, the source (and source for major disagreement) is

> far removed from our discussion section. We could then consider the
> input source as just another node for as long as we wanted.

I'm happy to entertain an alternative analysis. The result should be the same as mine, however, which the SPICE model shows to be correct.

Perhaps some readers don't realize that the SPICE model isn't just a graph of the equations I derived. It's a circuit simulator which uses fundamental laws to show the behavior of circuits. The SPICE model consisted only of two transmission lines both having the same impedance and connected in tandem (so I could show the voltage one wavelength from the input), a perfect voltage source, and a 1 megohm terminating load which is necessary because SPICE has problems with a completely open circuited transmission line. It knew nothing of my analysis or equations, yet it produced an identical result.

> Traveling waves easily explain standing waves on a 1/2 wavelength
> section, as you demonstrated. Maybe they can explain or clarify more
> things if we can get past "hang ups" such as the " -1 reflection at a
> perfect voltage source".

Who's "we"?

The analysis procedure I illustrated can be used to derive all the steady state transmission line formulas, including ones describing standing waves; voltage, current, and impedance transformation; delay; and so forth. It can even be used when loss is present, although the math gets a lot stickier. Only one additional step is necessary to find the steady state solution, and that's to find the sum of all forward waves to get a single combined forward wave and likewise combine all the reverse waves into a single reverse wave. This can be done with a simple formula for summing an infinite series, because each reflected wave bears the same relationship to its original. There are usually much easier ways to get a steady state solution, but this approach allows seeing just what happens as the line is charged and the waves are created.

Consider the electric field, for example. Like charge,
two fields of the same polarity will exert a force on
each other. Arguably, this is the same force that
charge exerts.

Also consider that field lines never cross. It would
therefore seem impossible for the two electric fields
associated with two EM waves to pass each other

without interaction. Just like the places on the transmission line where the voltage or current (and therefore power) is always zero, there are places in space where the E or H field (and therefore power) are always zero.

And whether the wave in space is viewed as passing or bouncing, the results should be the same, just as it is on a transmission line.

That's an interesting and compelling argument. With the conditions you describe, I don't see how it would be possible to tell whether the waves reflected from each other or simply passed by without interacting.

But suppose we launch waves of different shapes from the two directions, say a triangular wave and a rectangular one. Or perhaps make them asymmetrical in some fashion. It seems to me that then we should be able to tell which of the two possibilities happened. Being different, you could argue that the reflection wouldn't be complete. But shouldn't we expect some distortion of any part of a pulse that was acted upon by the other?

I'll put my money on each of the waves arriving at the opposite end unchanged. What do you predict will happen?

Sorry, I can not follow the numbers. For frequency of 1 MHz, I would
expect w = 2*pi* 10^6 = approximately 6.28 * 10^6 radians per second.
100 ns would be about 0.628 radians = 36 degrees.

The wave would have moved 36 degrees.

A point in 20 degrees from the input end would be found 16 degrees
behind the leading edge of the wave. The voltage should be sin(16) =
0.276v.

I wonder why we can not get the same results?

I have never seen the derivation that supports a negative 1, and still
can't get the same numbers that you get. The derivations that I have
seen say otherwise.

I don't think you mean vector addition here. As you said previously,
the traveling waves add voltage when they pass. That would be scaler
addition.

I agree that one wave does not change the other. It looked to me like
you were using SCALER addition in your analysis, which I agreed with.

The "perfect voltage source" controls or better, overwhelms any effect
that might be caused by the reflected wave. It completely defeats any
argument or description about reflected waves.

When you use a "perfect voltage source" with a -1 reflection factor, you
are saying that a perfect polarity reversing plane (or discontinuity)
exists which reflects and reverses the reflected wave. However, the
reflecting plane (or discontinuity) is one way because it does allow
passage of the forward wave. This is equivalent to passing the forward
wave through a rectifier. Is it fair to our discussion to insist on
using a voltage source that passes through a rectifier?

We could use a "black box" wave source. The only thing we would know
for sure about this source is that when it fed a Zo resistor through a
Zo feed line, there would be no swr on the feed line. Would that be an
acceptable voltage source for our discussions?

I followed your analysis and thought it very well done. My only concern was the "perfect voltage source". I think that using a source voltage that has effectively passed through a diode destroys the results of a good analysis.

If you mean for the calculation of the voltage at 100 ns and 20 degrees down the line, it's because of my error. It should be sin(36 + 20 degrees) ~ 0.83.

It's not clear to me what the problem is. Do you mean that you can't get the same end result for the voltages and currents on the line at various times? The results I got were confirmed with the SPICE model, so I have high confidence they're correct. If you're using some reflection coefficient other than -1 at the source, it's not a surprise that your final results would be different.

As I mentioned, time domain analysis of transmission lines is relatively rare. But there's a very good treatment in Johnk, _Engineering Electromagnetic Fields and Waves_. Another good reference is Johnson, _Electric Transmission Lines_. Near the end of Chapter 14, he actually has an example with a zero-impedance source: "Let us assume that the generator is without impedance, so that any wave arriving at the transmitting end of the line is totally reflected with reversal of voltage; the reflection factor at the sending end is thus -1." And he goes through a brief version of essentially the same thing I did to arrive at the steady state.

I should have said phasor rather than vector addition, a mistake I've made before. You can add the waves point by point at each instant of time, in which you're doing simple scalar addition. Or you can add the phasors, which have magnitude and phase like vectors, of the whole time-varying waveforms at once.

> argument or description about reflected waves.

If you'd like, I can pretty easily modify my analysis to include a finite source resistance of your choice. It will do is modify the source reflection coefficient and allow the system to converge to steady state. Would you like me to? There's no reason the choice of a perfect voltage source should interfere with the understanding of what's happening -- none of the phenomena require it.

> When you use a "perfect voltage source" with a -1 reflection factor, you
> are saying that a perfect polarity reversing plane (or discontinuity)
> exists which reflects and reverses the reflected wave.

Yes, it behaves exactly like a short circuit to arriving waves.

> However, the
> reflecting plane (or discontinuity) is one way because it does allow
> passage of the forward wave. This is equivalent to passing the forward
> wave through a rectifier. Is it fair to our discussion to insist on
> using a voltage source that passes through a rectifier?

The voltage source isn't acting like a rectifier, but a perfect source. It resists as strongly as it can any change to what it's putting out. I'm using superposition to separate what it's putting out from the effects of other waves.

> We could use a "black box" wave source. The only thing we would know
> for sure about this source is that when it fed a Zo resistor through a
> Zo feed line, there would be no swr on the feed line. Would that be an
> acceptable voltage source for our discussions?

I have no problem with a "black box" source for which we know only the voltage (as a function of time, e.g. Vs * sin(wt) where Vs is a constant) and source impedance. The voltage is the open terminal voltage of the black box, and the source impedance is that voltage divided by the short circuit terminal current. One circuit (of an infinite number of possibilities) having these characteristics is the Thevenin equivalent, which is a perfect voltage source like I've been using in the example, in series with the specified impedance. But for the analysis I won't need to know what's in the box, just its voltage and impedance. Analysis with any finite source (or load) resistance is easier than the no-loss case because it allows convergence to steady state.

But the source resistor has no impact whatsoever on the transmission line SWR -- it's dictated solely by the line and load impedances. So you'll have to think of some other criterion to base your choice on.

If you want "no SWR" (by which I assume you mean SWR = 1) on the line, the only way to get it is to change the load to the complex conjugate of Z0. But then the analysis becomes trivial: the initial forward wave gets to the end, and that's it -- steady state has been reached. Finished.

> I followed your analysis and thought it very well done. My only concern
> was the "perfect voltage source". I think that using a source voltage
> that has effectively passed through a diode destroys the results of a
> good analysis.

Well, the results are correct. But as I said, this doesn't guarantee that the analysis is. I welcome alternative analyses which also produce the correct result.

I'm sorry you can't get around the concept of separating the source output from its effect on returning waves. Superposition is a powerful technique without which an analysis like this would be nearly hopeless to do manually. The source isn't "rectifier" at all and, in fact, introducing any nonlinear device such as a rectifier would invalidate most if not all the analysis, and eliminate any hope that it would produce the correct answer. The fact that it does produce the right answer is strong evidence that no nonlinear devices are included. But if adding a source resistance would help, I'll do the same analysis with a source resistance of your choice(*). Shoot, you can do it too. Just change the source reflection coefficient from -1 to (Zs - Z0) / (Zs + Z0) using whatever Zs you choose. The steps are the same, but you'll see that the reflections get smaller each time, allowing the system to converge to steady state.

(*) You could, of course, put a pure reactance at the source. But then we'd end up with a source reflection coefficient having a magnitude of 1 but a phase angle of + or -90 degrees, and still get a full amplitude reflection and no convergence. A complex source impedance (having both R and X) would give us a reflection coefficient of less than one, and convergence, but make the math a little messier. So I'd prefer a plain resistance if it's all the same to you.

OK ...

I have this nice brass pipe and fittings, a couple of copper disks ~6in.+ to solder at the ends, etc.

Now, if I construct this tank for, say 10m, and it is ~28-32 inches in physical length, and tuned with a cap at the end, how can I know where the standing waves are/is? Should I "picture" this as if it were a real 1/4 wave at 10m, and the wave is "compressed?" ... Your best ideas? Knowledge? What the heck did those gurus' say in their books? I mean, I am going to have to drill a hole or two to get that 1 turn loop in their to couple to something ...

I have gotten to this point, I thought it would be apparent ... need some help. Without having to admit you are not a guru, got any pointers?

A friend in need ... I think they (the standing waves) are going to be trapped in there though :-)

Got any ideas? I mean, just help getting me started ...

[pictures will follow at a later date to get us "all on board."]

I hate to say this, but on the first point, you are wrong. people do, in fact, do digital voice on HF (just tune into the frequencies quoted on the AOR info page).

now, as for the second part, bpl can be reduced by other techniques (such as inverting the phase of the received bpl 'noise' by use of a sense antenna and some DSP technology (some experimentation required here).

so? how well does your assertion stand up now?
until you experiment and seek the truth of this problem, you just won't know (and belief isn't sufficient).

and now the other side of the coin....

Digital may have superior Quality as far a reproduction goes, but, IF the interference is strong enough, it won't really do any good (SNR too low for proper lock/decode).

> I'll put my money on each of the waves arriving at the opposite end
> unchanged. What do you predict will happen?

I predict that the pulse arriving at the left end will have the same voltage, current and energy profile as the pulse launched at the right end and the pulse arriving at the right end will be similar to the one launched at the left.

They will appear exactly AS IF they had passed through each other.

The difficulty with saying THE pulses passed through each other arises with the energy. The energy profile of the pulse arriving at the left will look exactly like that of the one launched from the right so it will seem that the energy travelled all the way down the line for delivery at the far end. And yet, from the experiment above, when the pulses arriving from each end have the same shape, no energy crosses the middle of the line.

So it would seem that the energy that actually crosses the middle during the collision is exacly the amount of energy that is needed to reconstruct the pulses on each side after the collision.

If all the energy that is launched at one end does not travel to the other end, then I am not comfortable saying that THE pulse travelled from one end to the other.

But I have no problem saying that the system behaves AS IF the pulses travelled from one end to the other.

On the other, it is completely intriguing that a directional voltmeter could be placed anywhere on the line and the voltage profile of the two pulses can be recovered. And this is true even at the middle of the line where, in the experiment with identical pulse shapes, no current flows and no energy crosses. But the shape of the two pulses can still be recovered.

So in the end I say it is AS IF the voltage and current pulses pass through each other, but the energy does not necessarily do so. That way I am not left with having to account for where the reflected energy goes when it arrives back at the source.

John

Okay so lets take you assertion one step further. Lets get away from BPL and (nasty) interferring noise and go to (say) 70cm where Boltzman's constant is more the limit. In 2kHz of bandwidth there is around -141dBm of (terrestrial) signal level present as random noise. Amongst VHF/UHF SSB's purists this is the limit which is generally accepted as impossible to go past with normal techniques. It is true that you can go better than this but only by reducing the effective bandwidth. Using something like MT63 uses an FEC mode of repeating the same message over and over, using QRSS just uses a much narrrower bandwidth. Both can be plugged into the standard SSB RX (noisy) output but limit the effective bandwidth by the nature of their decoding method. QRSS30 for example will (visibly) decode maybe to -170dBm or so.

Error coding/compaction also reduces the effective bandwidth. These are well known and used techniques for digital signals. CDMA phones for example have the strange method of applying more and more CPU time to decode a noisy signal. They apparently reach the theoretical Boltzmanns for the used RF bandwidth.

A good codec will definitely give you "some" improvements. This works extremely well and predictably over a "pure" digital environment (like VoIP) On the other hand however a digital decoder always needs a better S/N than the human ear/brain combination. VHF/UHF SSB operartors I have heard talk about 1dB above the noise floor as being able to resolve speech.

Yes I am aware that cheap PC hardware is available for this. I use it myself for many things. A good reference for the problems associated with sound card dynamic range (and other issues) can be found on the Linrad and baudline websites. They are both excellent reading.

Please be specific as to your experimental results John. The tests you need to do can be done with a couple of PC's and maybe even an "air" link speaker to microphone. You should easily be able to produce an audio speech signal and add noise to it so that you can emulate a reference at a low S/N. (Audacity will let you do that) Create a few of these at differring noise levels for comparison, Now repeat the exercise creating a pure digital signal and adding the same noise levels to that prior to decoding. You should be able to post your results to a webpage somewhere showing 3-4 analogue and 3-4 digital for others to compare.

I am sure that others will have a great interest in your results.

Cheers Bob VK2YQA

While I wrote the above about the energy in the
pulse not flowing all the way across the line,
the same can be said for the charge. The charge
which describes the pulse does not all go across
the middle of the line; just enough charge
flows to reconstruct the pulse on the other
side.

So the similar question is: Is it the same pulse
if it is not the same charge? Or is it another
pulse that just happens to have the same shape?

I understand where you are coming from, but again it is about a contra
winding
portion of the trap which one knows does melt.A better way to do the
same job
would be to have a 20M half wave dipole with a square loop at the
center
with a variable capacitor. When you are at 10 M you then get double
the radiation
instead of loosing it to the traps. The variable capacitor gives you
dexterity
with respect tocontinual resonant frequencies.
Try it you will like it.

Don't feel unique - I do the same thing when someone
says God created the heavens and earth in 6 days.

You are either confused about what I said (or deliberately
bearing false witness). Please correct your confusion
(or lack of ethics) or I will stop responding.

Bottom line: At points '+' in the example before any
cutting, either reflections exist or they don't.

If reflections exist, there has to exist an impedance
discontinuity to cause the reflections. There is no
impedance discontinuity.

If reflections don't exist, there is nothing to change
the direction of the flowing energy. Therefore, energy
is flowing both ways through the '+' points. The *NET*
energy flow is zero. But it is easily proven that
energy is flowing from one SGCL to the other.

If your model requires EM waves to bounce off of
each other, it doesn't represent reality. What
you may be seeing is the case where destructive
interference in one direction has to equal constructive
interference in the other direction. This is simple
wave cancellation, not bouncing.

The reason that the logic eludes you, Roger, is that it
can exist only in the human mind where anything is possible.
Roy's above statement requires a belief in the supernatural.

The impedance of a real world source is never zero and
Roy cannot leap tall buildings at a single bound except
in his mind. :-)

Sorry, it wasn't meant that way. It is just a fact of
physics that is obvious. EM waves possess energy and
momentum. Both of those values must be preserved. In
a passive constant-Z0 transmission line, if there are
no impedance discontinuities to cause reflections, then
reflections cannot exist. If reflections don't exist,
the momentum of the EM waves doesn't change.

If it doesn't happen with light waves, it probably doesn't
happen with RF waves - they are identical except for
wavelength.

I am stating a negative premise, that EM waves do not bounce
off of each other. A negative premise cannot be proved. It
can only be disproved and it only takes one case to do so.

If anyone can offer just one proven case of one EM wave bouncing
off of another EM wave in the complete absence of a change in
the media, then I will be proven wrong.

They engaged in typical author-speak. My university professors had no such limitations. They were quite harsh on anyone who tried to figure out where the power goes inside a Thevenin or Norton equivalent source.

> It is not I who wants it both ways. For me it is clear
> that there is no reflection when the output (source)
> impedance is the same as Z0. And when it is not equal
> to Z0, there is a reflection.

Apparently that is NOT clear to you. In the earlier example, there is no impedance discontinuity at the '+' points, yet you require reflections at those points. That's what you cannot have both ways.

If there's no traveling wave energy flowing through the '+' points, there must exist reflections. If reflections exist, there must exist an impedance discontinuity. There is no impedance discontinuity.

> Not when the output (source) impedance is known. It is
> then easy to compute the magnitude of the reflection
> using the standard rules for reflection coeficient.

Although many have tried to prove that the output (source) impedance is the impedance encountered by the reflected waves, all of those numerous experiments have failed. Therefore, there is a high probability that the impedance encountered by the reflected waves is *NOT* the output (source) impedance. The argument has raged loud and long since at least the 1980's. You are not going to resolve it by hand-waving.

Keith, if you can prove that the reflected waves encounter the output (source) impedance, you are a better man than all of the many others who have tried and failed.

They certainly superpose so the field lines don't
cross but superposition doesn't cause interaction
in free space or in a constant-Z0 transmission line
where neither medium changes. Free space superposition
results in zero reflections.

Any "view" is possible in your mind but not every
view of yours that is possible is associated with
reality. Your view could just as easily be the
same as my mother's (RIP), i.e. that God is
responsible for everything.

If your view is disassociated from reality, it is
no better than a religion.

The impedance of the perfect voltage source is supposed
to be zero. I, like you, suspect that is a complete
impossibility. What I would like to see is a TV signal
fed through a source only to emerge unscathed on the
other side and viewable on a TV screen without distortion
just as the theory predicts.

>elevator shack.

Hi Myles,

You first need to differentiate between radiated noise and conducted noise - you obviously know where the source is.

To conducted noise:

Does the SGC share the same ground as the switching loads for the elevator? If so, you want to find another ground. ANOTHER ground? A jillion floors above earth? What does ground mean in that context?

The path for the motors' heavy current is through a wire. That wire has resistance (however small). The current through that resistance elevates "ground" above the normally placid and noiseless ground with a hash of voltage noise that goes right into anything SHARING that path (and also having alternative paths to the same ground - it is quite common).

Finding another ground can be approached through two ways: randomly, or analytically. Analytically can be masked by failures due to what is perceived to be ground (that is how this all began). Randomly dooms you to useless repetition in the guise of a new choice being a different choice (often quite rare). Random has the benefit of being quick and luck may come your way suddenly (it can also vanish just as fast when something changes - this how all this began).

Analytically: Where do you ground things on top of the elevator shed? Move that to wire it to a more remote point. If you don't ground anywhere on the roof, then we move on:

To consider radiated noise:

This is the same noise being coupled through the air. If you don't ground at the roof, then you might have long conductors that run in close proximity to the heavy current burdened wires of the motors. If so, then you will want to choke your wires going down to your shack. ALL OF THE WIRES GOING TO YOUR SHACK. You may need to do this repeatedly along their length. You are going to get an education in Ferrites if this proves to be the solution.

As an aside:
>the new stuff i ckt

>boards inside of metal boxes
If you can, closely examine those boxes to see if they have a separate ground wire. Follow it where ever it might go. This might identify a quiet ground, or a noisy ground point for you to try to tie into as part of your experimentation. Similarly, If you can, closely examine those motors to see if they have a separate ground wire. See if they go anywhere you can use, or avoid as the conditions of experimentation reveals.

Don't give up! I've been reading some of the old ARRL Antenna
Handbooks. You're a mechanical guy. I see a chain drive going though a
wall, rigged to be aimed using the steering wheel from a '60 Impala.

I'm thinking we could rework that rope-tuned slinky idea into something
commerically marketable if we use steel cable and stepper motors. We
could call it the "Erstepp" or something like that.

From the equation vf(t,x) = sin(wt-x), I am getting
vf(36 degrees, 20 degrees) = sin(36-20) = sin(16) = 0.276v.

Could we look at five points on the example? (The example has frequency
of 1 MHz, entered the transmission line 100 ns prior to the time of
interest, and traveled 36 degrees into the line) Using zero voltage on
the leading edge as a reference point on the sine wave, and the input
point on the transmission line as the second reference point, find the
voltage at (36, -20), (36, 0), (36, 20), (36, 36)and (36, 40). All
points are defined in degrees.

Not on the line yet, at -20 degrees, sin(36+20) = 0.83.
At line input, at 0 degrees, sin(36+0) = 0.59v.

On the line, at +20 degrees, sin(36-20) = 0.276v.
On the line, at +36 degrees, sin(36-36) = 0v.
On the line, at +40 degrees, sin(undefined, -40) = (wave has not arrived)

Each of us must be using a different reference point because we are
getting different results.

I wonder if it is possible that Johnson, _Electric Transmission Lines_,
presented an incorrect example? That occasionally happens, but rarely.

Or maybe some subtle condition assumption is different making the
example unrelated to our experiment?

Just for conversation, we could place a 50 ohm resistor in parallel with
the full wave 50 ohm transmission line, which is open ended. At
startup, the "perfect voltage source" would see a load of 50/2 = 25
ohms. At steady state, the "perfect voltage source" would see a load of
50 ohms in parallel with "something" from the transmission line. The
power output from the "perfect voltage source" would be reduced below
the startup output. We would arrive at that conclusion using traveling
waves, tracing the waves as they move toward stability.

Would it be acceptable to use a perfect CURRENT source, along with a
parallel resistor. Then CURRENT would remain constant, but voltage
would vary. Again, power into the test circuit would vary.

When we define both the source voltage and the source impedance, we also define the source power. Two of the three variables in the power equation are defined, so power is defined.

Now if the we use such a source, a reflection would bring additional power back to the input. We would need to begin the analysis all over again as if we were restarting the experiment, this time with two voltages applied (the source and reflected voltages). Then we would have the question: Should the two voltages should be added in series, or in parallel?

Your answer has been to use a reflection factor of -1, which would be to reverse the polarity. This presents a dilemma because when the reflected voltage is equal to the forward voltage, the sum of either the parallel or series addition is zero. You can see what that does to our analysis. Power just disappears so long as the reflective wave is returning, as if we are turning off the experiment during the time the reflective wave returns.

Would a "perfect CURRENT source" without any restrictions about impedance work as an initial point for you? That would be a source that supplied one amp but rate of power delivery could vary.

My thinking keeps evolving, so new twist emerge.

If the impedance of the perfect source is zero, what limits the power output from the source? If the limit is supplied by the load, then the perfect source has evolved into a real source as soon as the circuit has been defined.

All that is required to achieve resonance in a distributed
network is that (in phasor notation) (Vf+Vr)/(If+Ir) be purely
resistive. Use your imagination to figure out if that always
implies 90 degrees.

An important point is that a reflection would bring
additional *energy* back to the input, not necessarily
power to the source. If the energy is re-reflected, it
will *not* appear as power in the source.

Now there's a bit of a pickle. You previously agreed
that
P(x,t) = V(x,t) * I(x,t)
but now you claim that there is energy flowing.

If you do not accept that P = V * I, please clearly
state so. The discussion could then continue with
the more basic issue.

> The *NET* energy flow is zero.

NET energy flow is not defined in your favourite
reference: the IEEE dictionary.

How does it differ from "instantaneous power" for
which the IEEE does have a definition (P=V*I, if
you are interested)?

> But it is easily proven that energy is flowing
> from one SGCL to the other.

It would be wonderful if you could provide this
easy PROOF since such a proof would settle the
question.

The reflection coefficient for a short is -1, is it not?

One way of viewing a short is that it is a perfect
voltage source (i.e. 0 output impedance) set to 0
volts.

Setting it to some other voltage (or function describing
the voltage) does not alter its output impedance. It
there fore creates the same reflection of the travelling
wave, regardless of the voltage function it is generating.

A real world voltage source has an output impedance. Use
this impedance to compute the reflection coefficient.
The reflection will be the same regardless of the
voltage function being generated by the source.

No pickle at all. Any rational person would agree
that if we have 10 joules flowing in one direction
and 10 joules flowing in the other direction that
the *NET* power is zero and the *NET* energy flow
is zero.

When you look at yourself in the mirror, there is
just as much energy flowing toward the mirror as
is flowing away from the mirror yet you see your
image. Do you really think that the EM waves
flowing toward the mirror are interacting with
the EM waves flowing away from the mirror?

I already presented the proof. Establish a data
transfer between the signal generator and the
other resistor and then cut the connection. If
you assert that the data connection doesn't
go away, I feel sorry for you.

If the purpose of your argument is to confuse,
confound, and obfuscate, I fully understand why
you are presenting it. If your goal is technical
knowledge, then your approach is pathological.

Well, there is no energy flowing through the '+' points.
And I have no issue if you wish to claim that there
are reflections at these points, though I might use
'bouncing' to differentiate from reflections occuring
at points with non-zero reflection coefficients.

> If
> reflections exist, there must exist an impedance

You do seem to be trying to have it both ways.
No energy is flowing (q.v. IEEE definition of

instantaneous power), and yet you want energy
to be flowing.

> of the many others who have tried and failed.

Web references and Spice models which agree that "the
output (source) impedance is the impedance encountered
by the reflected waves" have been previously provided,
but you refused to explore them. If I recall correctly,
this was because they did not model the complexity of
an average ham transmitter so they were not of
interest to you. Since you have refused to explore
the question, you should refrain from making
pronouncements.

The impedance of a perfect voltage source IS zero.

How close humans can come to achieving such a device
depends largely on the budget.

Bench power supplies come quite close within their
current limits and single quadrant operation.

Spending more money will get you closer.

The fact that 0 can not be achieved does not detract
from their utility to assist understanding.

> sound like it is related to reality?

I think I would say it differently. I would describe the "perfect voltage source" as a variable impedance, constant voltage source, with all the impedance supplied by external loads. To my thinking, to define the perfect voltage source as having no impedance, and then using "no impedance" as an excuse to assign a negative reflection factor so that voltage from another source is inverted, is beyond belief. Not reality at all, as you say.

I can accept the concept of infinite power, and recognize the impossibility at the same time. It would do very bad things to a real circuit!

However, I can see the dilemma faced by a purist who sees 2v from a reflected wave (because the reflected wave has returned to the source and reflected as if it were an open end) and the 1v from the source at exactly the same location. Something must be wrong.

I don't recall any examples using perfect CURRENT sources. I think a perfect current source would supply a signal that could respond to changing impedances correctly. It should solve the dilemma caused by the rise in voltage which occurs when when a traveling wave doubles voltage upon encountering an open circuit, or reversing at the source.

What do you think?

Hi Richard,

A very good citation there. However, it might confuse Prior Arthur in the allusion to liquid.

However, to further the mysteries of diamagnetics, it would be interesting to read how Prior Art describes how water (a diamagnetic) refuses to radiate when his proposition is so heavily invested with that phenomenon.

Hi Roger,

I see a free mixing of "perfect" voltage and current sources, source impedances, black boxes, and what appears (above) to be a forced presumption of source power.

As is typical within these debates, something must be broken. For one, these "perfect" sources paired with an impedance specification necessarily describes a Thenvenin source (for some reason, no one sees the elephant in their living room here). For every Thevenin source, there is an equivalent Norton source; that, for either hidden within a black box, is indistinguishable from the other.

Given this equivalency, the forced power presumption collapses. Power in the black box (if in fact that is the intent of this coy "perfection") cannot be known.

That is a stretch of the imagination as real sources don't have any of
the characteristics of a fictitious "perfect" source.

Good point. The power disappears here, but energy transfer is evident
(we have current). We both have power and do not have power.

At the source, when the reflect wave returns and re-reflects, we have 2v
from the reflected wave matched with 1v from the source. We have both
1v and 2v.

OK.

Thanks for pointing out the short circuit voltage view. I had not
thought of that.

What would you think of using a perfect current source for these thought
experiments? My suggested perfect current source would supply only as
much current as could be absorbed by the load, so no power would be used
by the source, and current would be limited by the load.

I should quit before I get farther behind! In my haste I made a second error by adding rather than subtracting the 20 degrees. Again, you're correct and I apologize for the error.

I'll take extra care to try and avoid goofing up again.

> Could we look at five points on the example? (The example has frequency

> points are defined in degrees.

I'm a little confused by your dual reference points, both of which seem to refer to physical positions. In my analysis, I give an equation for a voltage as a function of both time and physical position. The time (t) reference point is the time at which the source is connected. At that instant, the sine wave source voltage is zero. The reference point for position (x) is the input end of the line. The voltage at any time and any position can be determined from the equation, provided that the wave being referred to has reached the position on the line at or before the time being evaluated (and provided that I don't make a stupid arithmetic error -- or two). You'll note that in my analysis, I usually give a time at which the equation is valid -- this is to insure that the wave has reached any point of interest on the line.

> Not on the line yet, at -20 degrees, sin(36+20) = 0.83.

The equation vf = sin(wt - x) isn't valid until the wave has reached
point x on the line. It's also not valid at any point not on the line.
So it can't be used under those conditions.

> At line input, at 0 degrees, sin(36+0) = 0.59v.

100 ns after turn-on, the wave has propagated 36 degrees down the line,
so it's present at the input end (x = 0) and the equation is valid. The
voltage at the line input is as you calculated, 0.59 v. at that time.

> On the line, at +20 degrees, sin(36-20) = 0.276v.

Correct.

> On the line, at +36 degrees, sin(36-36) = 0v.

Correct.

> On the line, at +40 degrees, sin(undefined, -40) = (wave has not arrived)

Correct.

> Each of us must be using a different reference point because we are

Certainly it happens, but both he and I get the same, correct result
using the same method. And it seems unlikely that both he and Johnk made
the same error.

> Or maybe some subtle condition assumption is different making the
> example unrelated to our experiment?

I'm not sure why you see this as necessary. Do you have an analysis
which correctly predicts the voltage at all times on the line after
startup but which uses some different interaction of waves returning to
the source? If so, please present it. I've presented mine and shown that
I arrived at the correct result.

> ohms.

No, at startup, the source always sees Z0, regardless of the load termination. The load termination has no effect at the source end until the reflected wave returns. And if the line is terminated in Z0, then there is no reflected wave and the source sees Z0 forever. To the load, a terminated line looks exactly like a plain resistor of value Z0. (I'm assuming a lossless line as we have been all along.)

> At steady state, the "perfect voltage source" would see a load of
> 50 ohms in parallel with "something" from the transmission line. The

> the startup output. We would arrive at that conclusion using traveling
> waves, tracing the waves as they move toward stability.

With the line terminated in 50 ohms, steady state is reached as soon as the initial forward wave reaches the load.

If the termination is some value other than Z0, the steady state impedance seen by the transmission line will be the load impedance (for our example one wavelength line or any line an integral number of half wavelengths long). When starting, the initial impedance is always Z0 for one round trip, for any line length. Then it will jump or down. With each successive round trip, the impedance will either monotonically step in the direction of the final value, or oscillate around it but with the excursion decreasing each time. Which behavior you'll see and the rate at which it converges are dictated by the relationship among source, load, and characteristic impedances.
>
> Would it be acceptable to use a perfect CURRENT source, along with a
> parallel resistor. Then CURRENT would remain constant, but voltage
> would vary. Again, power into the test circuit would vary.

The transmission line will react to a perfect current source in parallel with a resistance exactly the same as for a perfect voltage source with a series resistance. Put them in boxes and there's no test you can devise which can distinguish them by tests of the terminal characteristics. So yes, that's fine, or just a black box about which

the contents are completely unknown except for any two of the open
circuit voltage, short circuit current, or impedance. (It's assumed that
the box contains some linear circuit that doesn't change during the
analysis.) The results will be identical for any of the three choices.

> When we define both the source voltage and the source impedance, we also
> define the source power. Two of the three variables in the power
> equation are defined, so power is defined.

We define the maximum amount of power which can be extracted from the
box, but not the power that it's delivering. If we open circuit or short
circuit the box or terminate it with a pure reactance, it's delivering
no power at all. If we terminate it with the complex conjugate of its
impedance, it's delivering V^2 / (2 * Rp) where Rp is the parallel
equivalent load resistance and V is the open circuit voltage. With any
other termination it's delivering less than that but more than zero.

> Now if the we use such a source, a reflection would bring additional
> power back to the input.

This presumes that there are power waves bouncing around on the line.

We would need to begin the analysis all over
> again as if we were restarting the experiment, this time with two
> voltages applied (the source and reflected voltages). Then we would
> have the question: Should the two voltages should be added in series, or
> in parallel?

That's not a question I can answer, since it's a consequence of a
premise I don't believe. If your premise has merit, you should be able
to express it mathematically and arrive at the answer to the question.
Feel free to do an analysis using multiple sources and traveling waves
of power. If you get the correct answer for how a line actually behaves,
we'll try it out with a number of different conditions and see if it
holds up.

> Your answer has been to use a reflection factor of -1, which would be to

That's correct but no dilemma.

> You can see what that does to our
> analysis. Power just disappears so long as the reflective wave is
> returning, as if we are turning off the experiment during the time the
> reflective wave returns.

By "our" analysis do you mean my analysis or the one you propose?
There's no rule saying power can't disappear -- power is not conserved.
In fact, look at any point along the open circuited transmission line
and you'll find that the power "disappears" -- goes to zero -- twice
each V or I cycle. When you first turn on the source, the source

produces average power. In steady state, the average power is zero. It "disappeared", without any dissipative elements in the circuit. Energy *is* conserved, however, and there is no energy disappearing in my analysis. Feel free to try and conserve power in your analysis if you want. But energy had better be conserved in the process.

> Would a "perfect CURRENT source" without any restrictions about
> impedance work as an initial point for you? That would be a source that
> supplied one amp but rate of power delivery could vary.

Sure. The only difference to the analysis procedure would be to change the source reflection coefficient from -1 to +1, since a perfect current source has an infinite impedance. I don't know how it would affect the final outcome without going through the steps. Of course, the reflection coefficient for the current wave would go from +1 to -1, so I imagine you'd run into the same conceptual problem if you tried doing an analysis of the current waves.

continuing and expanding.

Maybe we should be considering a perfect POWER source, which could only emit power, never absorb it. The power out would be defined by load impedance, just as it is for the perfect voltage source.

> that these two pulses of charge bounce off each
> and head back from where they came.

Yet it sounds like you are saying that despite this charge repulsion and bouncing of waves off each other, each wave appears to be completely unaltered by the other? It seems to me that surely we would detect some trace of this profound effect.

> . . .

Is there any test you can conceive of which would produce different measurable results if the pulses were repelling and bouncing off each other or just passing by without noticing the other?

There are equations describing system behavior on the assumption of no wave interaction, and these equations accurately predict all measurable aspects of line behavior without exception. Have you developed equations based on this charge interaction which predict line behavior with equal accuracy and universal applicability?

A perfect voltage source has an output impedance of 0,
the same impedance as a short. The reflection
coefficient is -1.

The returning wave has a voltage Vref(t) which reflects
as -Vref(t).

So total V(t) at the output is
V(t) = Vsig(t) + Vref(t) - Vref(t)
= Vsig(t)

as expected.

> What do you think?

A perfect current source has an output impedance of
infinity, just like an open circuit. The reflection
coefficient is 1.

Similar to the reflected voltage for the perfect
voltage source, the reflected current cancels leaving
just the current from the perfect current source.

Why do you consider that to be necessary?

A very serious problem with this is that you've now got a nonlinear element, and we can no longer use linear circuit analysis and would have to resort to the basic time domain differential equations describing voltage and current relationships. Feel free to do the analysis; I won't do that one.

If your concepts of how a transmission line works can't handle simple cases like a perfect voltage source in series with a resistance, you might consider reexamining your concepts.

A perfect current source always provides the current
that it is set to regardless of the load impedance.
It does so by changing its output voltage.

(A perfect voltage source always provides the voltage
that it is set to regardless of the load impedance.
It does so by changing its output current.)

Doing the thought experiments with both voltage and
current sources is quite useful. The results are
always complementary, but I find that is solidifies
the learnings.

Real sources can be modelled as Thevenin sources;
that is, an ideal voltage source in series with
a resistor equal to the output impedance.

They can similarly be modelled as Norton sources;
that is, an ideal current source in parallel with
a resistor equal to the output impedance.

And a Thevenin source can be transformed into an
equivalent Norton source. Example...

A 100 V ideal voltage source in series with 50 ohms
has exactly the same output characteristics as a
2 amp ideal current source in parallel with a 50 ohm
resistor. Test using any load impedance: open, short,
any resistance value.

Either one is matched to a 50 ohm line (because
the output impedance is 50 ohms) and any reverse
wave will not be re-reflected but will disappear
into the generator.

...Keith

PS: The above descriptions generalize for impedances
that are not pure resistances but also contain
reactance.

I have been "in" digital RF systems for years John. Strangely enough
that kind of means I know how they work and the limitations there-in.

If you make grandiose assertions that imply you have somehow done better
with this mode than the rest of humanity, then you must provide proof.

Or patent and sell it!

Cheers Bob

So far I've seen a number of comments that claim my analysis is wrong for one reason or the other, in spite of the fact that it correctly predicts the line behavior as verified by SPICE. The main thrust of the arguments is that my analysis fails to agree with preconceived notions of traveling power waves and the invalidity of superposition.

Yet I've seen no alternative analysis or equations which correctly predict the startup line behavior by using other methods which incorporate these notions.

Why?

I make errors as well, so no criticism from here. I am just glad that
we are on the same page on how we use the equation.

As for the (36, -20) point, I was indeed specifying a point that had not
been supplied to the transmission line. It was a prediction, as if the
wave existed physically and was moving toward our experiment. We could
not actually observe it until time = 56 degrees.

> Roy Lewallen, W7EL

I agree that we would have the same problem with a perfect current
source which had an infinite impedance.

How about using a perfect POWER source, that could not absorb power.
Output power would be limited by the external impedance.
Mathematically, the perfect POWER source would be described by

Ps = (Vp^2)/Zvp = Zip * Ip^2 where Ps = maximum power output, Vp =
voltage from perfect voltage source, Zvp = 0, Zip = infinity, and Ip =
current from a perfect current source.

The power output could be infinite, but power could never be absorbed by the source.

Just as for both perfect voltage and perfect current sources, the actual power output would be limited by external loads.

The impedance of the perfect POWER source would be Vp/Ip, both controlled by external loads. To me that means that the output power from the perfect POWER source would follow the impedance presented by the load, but power going into the source would be defined as being zero.

Would the "perfect power source" be acceptable to you?

Thanks for this summary Keith. Discussion about traveling waves keeps getting trapped with reflected waves being inverted, absorbed, or disappear because of source problems. We end up discussing the source, not the traveling waves.

In a posting to Roy, I propose using a perfect power source, which would be a combination of perfect voltage and perfect current. The advantage is that output power would follow the load, not be permanently defined by the load like most consider to be the case for a perfect voltage or current source.

I won't repeat that posting here, but please comment.

No. As I mentioned on another thread, this is a nonlinear device, which would not permit using the linear circuit analysis I used. It would require reverting to fundamental differential equations, which I'm not willing to do. I'll be willing to use absolutely any linear source (which doesn't change during the analysis period) you can devise. Any linear source can be reduced to a Thevenin or Norton equivalent to produce identical results.

Can't your concept of transmission lines deal with linear sources? If not, why not?

I hate to totally block people who arguably have some useful things to post to the newsgroup. But the content on the thread about travelling waves versus standing waves has become so dominated by one person that there is no way to end it except by filtering all messages to rec.radio.amateur.antennas to eliminate the dominant poster. So I have not only blocked articles from his web site, I am blocking any article which contains his name. So if you reply to him, I am sorry but I will not be able to see your remarks. I know that no one is likely to lose any sleep about my actions. From now on, I hope there will be articles about antenna construction and modelling because that will probably be all that I am able to read. 73.

No, my concept of transmission lines deals fine with linear sources, it
is the non-linear constant voltage source and constant current source
that can not handle a second source of power arriving at a time later
than the original pulse.

Thank you for much thoughtful discussion. I have learned a lot, and sharpened my skills. I won't drop the topic, because it can bear great fruit, but let's you and I drop it for a while.

You may be right about differential equations needed for an perfect POWER source, but so far, I don't think so. I am being honest that I think your analysis applies up to the point of using the -1 reflection factor at the source. In fact, I will probably use it in the future, with an attribute to you.

Following Keith's post discussing zero voltage as a current source, I can see why you might insist on using the -1 reflection factor. As time passes, I will try to improve the concept of the perfect POWER source to see if that can bridge the conceptual differences, but retain the relative simplicity of sine waves adding.

I was afraid that a mathematical treatment wouldn't be appropriate for this forum -- it is, after all, an amateur newsgroup -- and it looks like I was right. It's taken a considerable amount of time to develop and present the analysis and answer questions as completely as I can, but it appears from the responses that the time was largely wasted. It's been my hope that at least a few "lurkers" have gained some insight from it. If so, please drop me an email letting me know one way or the other -- don't worry, I'll keep your email confidential. I'd been considering making up an analytical and quantitative analysis of where the energy goes in a transmission line. But it's certainly pointless if my analysis of even the most basic development of line voltage can't be understood or believed, as seems to be the case.

Hello Ken,

From your comment, it appears that you
are seeing all new posts to the group in
chronological order. That can be very
frustrating.

You may not be aware that most
newsreaders will sort messages by thread
if so instructed. That way an entire
thread consisting of even thousands of
posts will appear in your newsreader as
a single header (unexpanded). There are
usually no more than a few new threads
per day on the newsgroup so you can
choose which threads you want to follow
without seeing any posts to the threads
that don't interest you. Sort of like
scanning the headlines. When you see a
thread of interest, you can expand it
and see the headers of all the posts in
that thread.

You can't control which threads are
posted to the newsgroup, but you can
make it easier to read only those that
interest you.

73,
Chuck

Hi Roger,

That is not the problem of the sources, it is your problem alone in coming to terms with the network. Any reference that reaches deep into the fundamentals of lines and networks begins with the Thevenin source (and at least one off of my shelf delves into two Thevenin sources facing each other).
"There are waves of identical frequency traveling
in both directions on the line, but their amplitudes
and phases are independently variable,
and neither can be called "incident" or "reflected"
waves."

It is notable that the author expressly offers only one set of equations for the distributed voltage and current along a line and distinctly says:
"It is worth noting that (8.1) and (8.2) [those equations]
are also applicable to Fig. 8-2 below [showing the dual
source configuration with deliberate matches], a
distinctly different transmission line circuit."

What makes it "a distinctly different transmission line circuit" is that it is in fact one source feeding both ends. It settles the hash about frequency, phase, coherence, amplitude, matching, and all the other folderol that attends many of Cecil's jejune postings:
"Here a single source supplies signals to both ends
of a transmission line section, through networks that terminate
the section in its characteristic impedance at each end."

>As time
>passes, I will try to improve the concept of the perfect POWER source to
>see if that can bridge the conceptual differences, but retain the
>relative simplicity of sine waves adding.

The two equations, needing no reference to a constant power source:
V(z) = V1ï¿½ e^-yï¿½z + V2ï¿½ e^+yï¿½z
I(z) = (V1ï¿½ e^-yï¿½z - V2ï¿½ e^+yï¿½z) / Zo
where
z: the distance along a line

y = a + jB
a: nepers per unit length of line
B = 2 ï¿½ pi / wavelength
V1 & V2 are arbitrary voltage phasors to be determined by
boundary conditions at the ends of the line.

It took very little effort to then proceed to the obvious:
"Whenever two waves of identical frequency travel
in opposite directions on a transmission line ...
the fundamental phenomenon of interference or
'standing waves' occurs. ... exhibits periodic maxima
and minima ... in its most striking form when
the two oppositely directed waves have equal
amplitude and the transmission line system has
zero attenuation."

Elaborations of stepped pulses of energy had better resolve to
identical analysis using the math above, or the strain of elaboration
has led to sterile inventions.

It appears that his source is http://www.giganews.com which is web based.
They probably have options for sorting by date, thread etc. I think you are
correct. He should structure his viewing on giganews in such as a way as to
only view the threads of interest. He does noy use a normal 'newsreader'
like most usenet vets are using.

No, "John", an anonymous fellow like you is not required to provide any proof for anything he posts. Then again, those who have some knowledge of the subject aren't required to give credence to your views either.

Who they are is not guys going up against a BPL signal emanating from somewhere in the immediate vicinity of their locations.

> at points with non-zero reflection coefficients.

So bouncing is what happens at points with zero reflection
coefficients. You seem to have invented a new religion.

> No energy is flowing (q.v. IEEE definition of
> instantaneous power), and yet you want energy
> to be flowing.

Lots of energy is flowing in both directions.
Only the *NET* energy flow is zero.

I am not surprised that you are ignorant of the raging
arguments that have been going on primarily between
Bruene and Maxwell and their respective supporters.
I believe it continued to rage in the 2007 letters to
the QEX editors.

> Web references and Spice models which agree that "the

> but you refused to explore them.

No, I asked you to measure the reflection coefficients
and report the results. You refused to do so. If the issue
had ever been resolved, it would be common knowledge and
we wouldn't be arguing about it.

It can happen at a Z0-match point where destructive
interference exists on the source side and constructive
interference exists on the load side.

Here's an example:

Source-+---1/2WL 300 ohm line---50 ohm load

Assume the source voltage is 1 volt
The reflected voltage is ~2.5v
The forward voltage is ~3.5v
The load voltage is 1 volt

> I don't recall any examples using perfect CURRENT sources.

A Norton equivalent circuit is a perfect current source.

I have been using such a source as an example for years.
I call it the SGCL, signal generator equipped with a
circulator and load resistor. Here's the diagram.

```
100wSG---1---2----
\ /
3
|
R
```

No reflections incident upon the source because they
are all dissipated in the resistor R. It's a great
way to simplify examples.

Zero power dissipation in a Thevenin equivalent
source equates to maximum power dissipation in
a Norton equivalent source. That sure shoots
down any argument about dissipation in the source.

Indeed, take a look at the internal power dissipation
for an open and short and tell us again why those
sources are identical.

Your EM waves reflect when there is no reflective media.
That is a violation of the laws of physics. Please
demonstrate two light waves reflecting off of each other
in free space.

Roy, you wrote down the equation for V(x,t) for a
standing wave voltage. Now write down the equation
for I(x,t) for a standing wave current and tell us
again how to use that standing wave current with
its constant phase at different points up and down
the line, to measure the delay through the line.

Since Roy has ploinked me, he will ignore this posting.
Would some kind soul please reply to this posting so
Roy will see it? Thanks.

Will this source satisfy your needs? It is linear
and it prohibits reflected energy from reaching
the source making tracking energy rather simple.
I usually define it as a 50 ohm device but other
impedances could be chosen.

MI5 Persecution:. Molestation during Travel

MI5s persecution of. me varies in intensity. Since 1990 it has been steady for perhaps 80% of the time;. there was a notable quiet period in 1993, and another quiet period in Jan-Feb 1995, as. well as a hiatus in the first two months of 1999. It puzzles me that they. cease and restart, seemingly without any logic. or reason. But one aspect of MI5s activities against me which is. relatively predictable is this weeks articles topic, which is Molestation during Travel. Almost every. time I cross the Atlantic, go to the Continent. or even try to enjoy a holiday in this country, you can bet that MI5 will. be there doing their utmost to wreck it all.

This aspect. of the harassment is particularly relevant as I will be travelling to. Europe again in a months time, with naturally the Minidisc recorder in tow; so it will be interesting to see if I. can record the abuse which will almost certainly take place, either on the Tube. going to the airport, at the airport,. on the flight, in the terminal building - MI5 have previously instituted instances of. abuse at each of these locations, so well see how much taxpayers money they waste this time, and. whether it will prove possible. to capture their abuse on minidisc.

Read about the MI5 Persecution on. the Web

June 1992 in Polands mountain resort. of Zakopane

The persecution started. in June 1990, and for the first two years I stayed in the UK apart from a couple. of brief day trips to Calais. By the summer of 1992 Id had enough of. being cooped up in England with abusive fellow employees egged on by an abusive secret police service,. and decided to spend 10 days in southern Poland, on what was intended. to be a holiday at the mountain resort. town of Zakopane.

Unfortunately the. psychopaths of the Security Service were not willing to allow me. to enjoy a holiday in peace and quiet. The journey to Zakopane was by coach from the meeting point at Londons Victoria coach. station (National Express) followed by. ferry followed by another coach across Europe. As we left Victoria a youth and. his girlfriend started a loud tirade of abuse directed at. "this bloke", where the "bloke" was never named, but it was. very clear that the "bloke" was myself. The youth said "they" had "found somebody. from his school, and he was always really stressed at school, a real psycho".. Again, the label "they" was not elaborated. on, but it was clear that "they" = the persecutors from MI5. The boy also said, "he was in a. bed and breakfast for only one night and. they got him". By a not unexpected coincidence I had been in a B&B in

Oxford a week previously, which had been booked from work;. other things lead me to the conclusion that the company's offices. were bugged for most of the 2 1/2 years that. I was there, so "they" would have known a room in the B&B had been booked.. After a few minutes of this I went back to where they were sitting and asked where they were. travelling. The boy named a village in France, and the girl's giggling. suddenly ceased; presumably it permeated to. her brain cell what the purpose of the boy's abuse was.

It is now very clear to me. that MI5 were trying to have me incarcerated, assaulted or killed on this trip across Europe.. The degree of verbal violence inescapably leads to this conclusion. When. we arrived at our destination, it. became clear that many people, both in our tour group and its guide, and among the ordinary residents of the town, knew there was. a movement under way to "get". me. MI5 employed many people and significant resources for an action which they knew would only take a. maximum of ten days. A commercial operation would never have felt. able to waste such resources on such an unproductive and temporary action; only. a state-sponsored, taxpayer-funded entity like the Security Service would. be able. to be so wasteful.

To give some examples of what happened in those ten days; I was walking. in some woods outside the town, when a Polish woman,. looking at me, said the English "shit" in a strongly Polish-accented. voice. For the first three years 1990-92 MI5 had been. trying to force this word on me. Another example; I was walking near my. "hotel" when a mother said laughing to her child, "a wiesz. ze to prawdziwy wariat" which means "you know hes a real madman". And the "TV reacting" happened there too;. on Polish TV, a bemused looking journalist said to another, "to jest sprawa Anglikow",. which means "its the concern of the English", in other words, none. of our business, despite what the English are. trying to force down our throats.

Just before we left for home, I went with some others. from our group to a nearby. bar. There a man shouted at me the same sexual obscenity which MI5 have. constantly thrown at me these last three years. I think MI5 try to justify their. various terms of abuse by repeating them at me until I say them, either while conscious. or while talking in my sleep; and then they seize on my saying those words to "prove" that. the obscenities are "my fault", et cetera. This rather stupid reasoning of theirs can. actually be seen as indicative of the psychopathic condition attributed. to them in a previous article; blaming the victim for the crime you inflict on him. is how. psychopaths think.

Nor did. the persecutors let up during the return trip. Returning on the ferry over the. channel, a rather insalubrious-looking guy talked to his mates. about "and you know this bloke, hes really mad you know, hes really mad". On the National. Express return coach to London, a group of five or six young. people started shouting at me. I slumped in my seat and tried to avoid presenting a target, so they got. ever more strident - "whats the matter with you, cant you hear us?" One of the. other people who had been on the trip to Poland asked them. why they were shouting at me, and they said, "hes been to Cambridge", to which the co-holidayer. asked them, "have

you been. to Cambridge?" presumably thinking they were aggrieved fellow students, but they answered "no". Even after I. left the coach at Elephant and Castle abuse continued; in. the tube station, two kids started throwing abuse at me; one of them said to the other,. "and you know he works?" to which the other. answered "yes".

Immediate Aftermath of November. 1992

As you will know from previous articles, my manager. at OCG - ARIS/Oxford, Mr. Mitchell, induced a mental breakdown in me in the months leading up to Nov/92. The. diagnosis was regarded by the persecutors as a victory for them, because few if any people give credence to allegations of. harassment when they are. made by somebody suffering from schizophrenia. There is also a bias. against the mentally ill, an "institutionalised bigotry" in society comparable to the. institutionalised racism against blacks.

However, MI5. did not let up on persecuting me following Nov/92. In December 1992 I flew by charter jet to Alicante. in Spain for two weeks recuperation. MI5 planted one of their people on the flight,. a youth who tried to start some noises that "hes. a nutter". One of the other passengers. replied, "oh hes a nutter is he? oh well!" and the youth shut up and said nothing. for the rest of the flight. I think it would be fair to say that the. youth on the flight was embarrassed by what he had been asked to do in making the flight "uncomfortable" for. me; he sounded defensive. rather than aggressive.

My first trip. to Canada in June 1993

Ive already covered this in a previous. article so Ill just give a brief summary here. On 10 June 1993 I. flew British Airways from Heathrow to Torontos Pearson Airport. On de-planing. from the aircraft, one of a group of four fellow passengers looked at me and said, laughing,. "if he tries to run away well find him". It was quite obvious that. these four men were the ones who had. been harassing me since 1990.

I did nothing to apprehend. them or bring this incident to the attention of the airport authorities, mostly because this was my. very first visit to Canada, and the last thing I wanted was to get into a. dispute before I had even finished disembarking. In retrospect, I can see this was a. terrible mistake;. I should have made every effort to detain and identify these people.

Subsequently I have made. numerous attempts to obtain the names of these people from British Airways passenger lists, by talking to. BA, through a lawyer in Ontario, through a. solicitor in England, through the UK police, and also through private detectives in the UK.. But all my efforts have come to nothing. BA have told me they keep passenger lists. for a period of seven years, so they will still have the. list for this 1993 flight. I did not see or hear anything during the rest of. my visit to Ontario in 1993 which would have lead. me to believe that I was being watched or followed.

Journey. across Canada in summer 1994

As I. think Ive already said in previous articles I emigrated to Canada in late. May 1994. For six weeks between late May 1994 and early July 1994 I travelled across. Canada from coast to coast, starting in Toronto, visiting various cities and ending up in British Columbia. I. saw this both as something of a holiday,. and the chance to get to know a little better my adopted. country.

As you can guess, MI5 followed me everywhere I went during these. six weeks. In Toronto, where I started. this trip in late May, I was spoken about by one youth. to another with the words "hes an idiot", to which the other replied, laughing sympathetically, "good luck. to him".

A couple of days later I went. to Montreal and stayed at the YMCA downtown. As you can guess. (this is all so predictable, isnt it?) MI5 followed me. there and bugged my room at the YMCA. Not only that, but they managed to set-up an instance of "newscaster reaction" from. a local television station; while I was watching. a Vermont TV news programme on the set in my room, the woman. reporter said, "well theyre just tired and they want. to go home", which sounds like a pretty unprofessional thing to say until you. realise she was trying to say of me that I was the one that was supposed to be tired, and they (ie MI5) wanted. me to go home to the UK.

On. the bus journey across the North American continent, it was quite clear that MI5 were following me every step on the way. For the. first part of the journey they. actually put someone on the bus with me, a youth who said at me "that guys paranoid" and tried to incite other passengers to. attack me. I stopped. for a couple of days in Winnipeg in central Canada, and on leaving the town heard on the. radio a female presenter ranting about "insanity!. insanity!". It is very tiring travelling such a long distance by bus; I took the journey in two steps, each of about. 36 hours; and it is especially tiring when you know MI5 are watching. you and harassing you every step. of the way.

When. I finally got to Vancouver, MI5 instituted the usual harassment, in very short order. I was surprised how quickly. they were able to induce hatred towards me in elements of the. general populace; the Security Service must have employed a number of agents and serious. resources in a very short period of time; and for no real gain, because. I havent been back to BC for almost five years, so all their "work" appears to be. for nothing. In downtown. Vancouver a street person said in front of me, "theyre all talking. about him". For a few days I was staying at Pauls Guest House (345 W.14th Ave); on the. day I left, the owner Paul shouted at no-one in particular, "hes going to Victoria" -. which was quite accurate, I. was indeed going to the provincial capital Victoria on Vancouver Island.. But I had not told anyone at the guest house where I was going; I had only mentioned to my parents back in England on the phone that. I was going away from Vancouver for a few days. Which leads. me to suppose that MI5s. bugging of the phone in my parents house yielded the "intelligence" that I intended to visit Victoria, and they. had passed the information on. to Paul.

When I got to Victoria it was again obvious that the persecutors. were "doing their. stuff" there as well. On the street I was identified as being English, although I had not said. anything so my accent hadnt given me away; and returning by ferry to the mainland,. I was abused by a Canadian woman who said, "hes a nutter! you can run but you cant. hide". During my years. in Canada I have never heard the word "nutter" on any other occasion; I do not think it. is part of Canadians vocabulary; so the Canadian woman on. the ferry, who was obviously talking about me, must have been supplied with this. word by the English persecutors. And once I got back. to Vancouver, staying at the Austin Hotel on Granville St, I listened to a conversation in the apartment block directly. opposite, and a man saying, "hes. paranoid, so thats as bad as it can be, so why are they doing this to. him?".

Holiday. in the States, August 1995

By 1995 I was living in Canada, and in August I went down the. eastern seaboard to Florida and as far as Key. West by car. As you can guess (this is all so boring and predictable, isnt it?) MI5 followed. me every step of the way. I can see in retrospect that this must have been quite. easy for them as they had my car bugged, both. on the inside to listen to anything that was said. and what radio station I was listening to, as well as what must. have been a tracker device installed to track it across long distances.

The first city I visited was Philadelphia. In the. old Congress Hall where the first US. Congress assembled, the woman guide started referring to my situation, saying that "all these people in. Europe were watching it", and they were "a little paranoid" at this 18th-century experiment. in democracy. Also I had recently written. a newsgroup post where Id described a (female) poster as "wet-nosed" (implying "canine"), and a young. girl in Philadelphia remarked,. "so he thinks were dogs?" There were two or three more incidents during this holiday in the eastern. States, including a radio station down near Miami,. showing "they" had tracked me all the way there, and were bugging the inside of. my car; but I didnt record the details and Ive forgotten some of. it now. Also down in Miami Beach a French tourist in a. lift expressed support for me with the words, "cest incroyable" ie. its incredible, meaning. that MI5s well-known actions against me. were beyond belief.

To go back a bit, in about May/June 1995 Id visited. New York, again by car, and was insulted. several times by people using the same words that had been used against me in England. In. Central Park, and elderly Englishman (not a real gentleman - but then the Engish. view of themselves as "gentlemen" etc is quite laughable) looked. at me and said "idiot". And while I was eating. in a streetside restaurant a New York youth started laughing. and said something like, "I cant believe it, hes actually here" - I think that was because I had had an expressed. wish to visit New York for some years before. this, although after this visit I wont be going there again for a. very long time.

Visit to Poland December. 1995/January 1996

In December. 1995 I flew (BA again, unfortunately - every time Ive flown BA one of these incidents has happened, presumably. MI5 is happier setting up harassment on British-domiciled carrier) from Montreal to Berlin. and travelled. on to Poland to visit family. MI5 naturally harassed me in Poland during. my brief stay. They followed me around and got Polish people to take part in the harassment. In. one case two Polish youths talked in front of me saying in English. (with marked Polish accents), "fucked up men, fuck you". There were. also other incidents which I dont remember too clearly since. it was some time ago.

The. return flight connected through Heathrow, and in the transit lounge MI5 again set-up harassment against me. In Poland they. were talking their abuse in English, and in London they set Polish people after me to. speak in Polish; they heard me on the phone. to my father, and said "a wiesz ze to Polski wariat",. in an almost sympathetic, inclusive fashion (translation. "you know hes a Polish nutter"). Once. on the flight to Montreal I was again set. upon by two English youths, one of whom spoke and the other listened. The aggressive "fat bastard". youth said, "if he wants to be a. wanker" (its my fault theyre harassing me, you see), self-justification that "hes a nutter" (so we have to keep on abusing. him, because hes ill), as well as talking about the. town in Poland where I had been staying. He also said, "he doesnt know who we are", but. as already remarked in a previous article, that was. at best a half-denial of my guess expressed in internet newsgroups that the people after me were MI5 -. if anything its a. half-confirmation rather than a half-denial.

These incidents are still going on. You can hear digitised. audio files of abuse on a BA flight to Berlin in 1998 on the Web at. address

On this flight they. were again attacking my mental health; "paranoid, hes paranoid" and "nutter". are discernable. The last "during travel" contact was at Ottawa Airport on 21 July 1998, when "Alan. Holdsworth" the psychopath MI5. agent, dressed as a vagrant, was pacing aggressively in the departure area. In three weeks I will again. be travelling to Europe; we will see what fresh. acts of molestation MI5 perpetrate during this trip.

MI5 are Afraid to Admit They're Behind. the Persecution

MI5 have issued. a formal denial of any involvement in my life to the Security Service Tribunal,. as you might expect them to; but, more importantly, the persecutors. have never denied that theyre from the Security Service, despite. several years of accusations from my corner on usenet and in faxed articles. I am not. surprised that the Security Service Tribunal found "no. determination in your favour". I am however a little surprised that. the persecutors have refused to confirm my identification of them; by doing so, they implicitly. admit that my guess was right.

"No determination. in your favour" says the Security Service Tribunal

In 1997, I made a complaint to the Security. Service Tribunal, giving only the bare outlines of my case. I do not think it would. have made very much difference if Id made a much more. detailed complaint, since the Tribunal has no ability to. perform investigatory functions. It can only ask MI5 if they have an interest in a subject, to which MI5. are of course free to be "economical with the truth". A couple of months after my. complaint the Tribunal. replied that;

The Security Service Tribunal have. now investigated your complaint and have asked me to inform you that no determination. in your favour has been made on your. complaint.

Needless to say this reply didnt surprise me in. the slightest. It is a well established fact that the secret service are a den. of liars and the Tribunal a toothless. watchdog, so to see them conforming to these stereotypes. might be disappointing but unsurprising.

It is noteworthy. that the Tribunal never gives the plaintiff information on whether the "no determination in your favour". is because MI5 claims to have no interest in him, or whether they claim their interest. is "justified". In the 1997 report of the Security Service Commissioner. he writes that "The ambiguity of the terms. in which the notification of the Tribunals decision is expressed is intentional", since. a less ambiguous answer would indicate to the plaintiff. whether he were indeed under MI5 surveillance. But. I note that the ambiguity also allows MI5 to get away with. lying to the question of their interest in me; they can claim to the Tribunal that they have no interest, but at a future date,. when it becomes clear. that they did indeed place me under surveillance and harassment, they can claim their interest was "justified". - and the Tribunal will presumably not admit. that in their previous reply MI5 claimed to have no interest.

"He doesnt know who we. are"

In early January 1996 I flew on. a British Airways jet from London to Montreal; also present on the plane, about three or four. rows behind me, were two young. men, one of them fat and voluble, the other silent. It was quite clear that these two had been planted on the aircraft. to "wind me up". The fat youth described. the town in Poland where I had spent Christmas, and. made some unpleasant personal slurs against me. Most interestingly,. he said the words, "he doesnt know who we are".

Now I find this. particular form of words very interesting, because while it is not a clear admission, it is only a. half-hearted attempt at denial of my guess that "they" = "MI5". Had my guess been wrong, the fat. youth would surely have said so more clearly. What he was trying to do. was to half-deny something he knew to be true, and. he was limited to making statements which he knew to be not false; so he made. a lukewarm denial which on. the face of it means nothing, but in fact acts as a confirmation of my guess. of who "they" are.

On one of the. other occasions when I saw the persecutors in person, on the BA flight to. Toronto in June 1993, one of the group of four men said, "if he tries to run away well find him". But the other. three stayed totally quiet and avoided eye contact. They did. so to avoid being apprehended and identified - since if they were identified, their employers would. have been revealed, and it would become known that it. was the secret services who were. behind the persecution.

Why are MI5. So Afraid to admit their involvement?

If you. think about it, what has been going on in Britain for the last nine years is simply. beyond belief. The British declare themselves to be "decent" by definition, so. when they engage in indecent activities such as the persecution of a mentally. ill person, their decency "because were British" is still in the. forefront of their minds, and a process of mental doublethink. kicks in, where their antisocial and indecent activities are blamed on the victim "because its his fault were persecuting. him", and their self-regard and. self-image of decency remains untarnished. As remarked in another article some time ago, this process is basically. the same as a large number of Germans employed fifty. years ago against Slavic "untermenschen" and the Jewish "threat" -. the Germans declared, "Germans are known to be decent and the minorities are at fault for what we. do to them" - so they were able to retain the view of themselves. as being "decent".

Now suppose this entire episode. had happened in some other country. The British have a poor. view of the French, so lets say it had all happened in France. Suppose there was a Frenchman, of. non-French extraction, who was targeted by. the French internal security apparatus, for the dubious amusement of French television newscasters, and tortured for 9. years with various sexual and other verbal abuse and taunts of "suicide".. Suppose this all came out into the open. Naturally, the French. authorities would try hard to place the blame on their victim - and in. their own country, through the same. state-controlled media which the authorities employ as

instruments of. torture, their view might prevail - but what on earth would people overseas make of their actions? Where. would their "decency" be then?

This. is why MI5 are so afraid to admit theyre behind the persecution. Because if they did admit responsibility,. then they would be admitting that. there was an action against me - and if the truth came out, then the walls would come tumbling down.. And if the persecutors were to admit they were from MI5, then you can be sure I. would report the fact;. and the persecutors support would fall away, among the mass media as well as among the general public.. When I started identifying MI5 as the persecutors in 1995 and 1996 there was a sharp reduction. in media harassment, since people read my internet. newsgroup posts and knew I was telling the truth. The persecutors cannot deny. my claim that theyre MI5, because then. I would report their denial and they would be seen as liars - but they cannot admit it. either, as that would puncture their campaign against me. So they are forced to maintain a ridiculous silence on. the issue of. their identity, in the face of vociferous accusations on internet newsgroups. and faxed articles.

Have MI5 lied to the. Home Secretary?

In order for the Security Services to bug my. home, they would either have needed a warrant from. the Home Secretary, or they might have instituted the bugging. without a warrant. Personally I think it is more likely that they didnt apply for a warrant. - I cannot see any Home Secretary giving MI5 authority to bug a residence to allow. television newscasters to satisfy their rather voyeuristic needs. vis-a-vis one of their audience. But. it is possible that the Security Service presented a warrant in some form before a. home secretary at some point in the last nine years, for telephone tapping or surveillance of. my residence, or interception of postal. service.

So the possibility presents itself that a. Home Secretary might have signed a warrant presented to him. based on MI5 lies. Just as MI5 lie to the Security Service Tribunal,. so they might have lied to a Home Secretray himself. MI5 and MI6 are naturally secretive services. former home secretary Roy Jenkins said, they have. a "secretive atmosphere ... secretive. vis-a-vis the government as well as [enemies]". Jenkins also said he "did not form a very. high regard for how they discharged their. duties".

It was only a few years ago that MI5 was brought into. any sot the extraordinary thing is that British media organisations like. the state- and taxpayer-funded. BBC take such an active part in the MI5-inspired campaign of harassment. We have after all heard of. MI5 trying to bribe broadcast journalists; but surely. there must be a substantial number who are not bought or blackmailed by the. Security Services, and who take part in the "abuse by newscasters" of their own volition? The BBC is. supposed to be independent of the government of the day. as well as the Establishment in general. While perhaps it is. childish to think that the BBC. is anything other than effectively state-controlled, the degree of

collusion between the BBC. and the British Secret Police MI5 is something you would not. find in many countries. Individual tele-journalists in other countries would. have enough self-esteem not to allow themselves to be controlled by their. secret police - seemingly, BBC broadcasters like Martyn Lewis and Nicholas Witchell have such a low opinion. of their employing. organisation that they see no wrong in dragging the BBCs no-longer-good name through yet more mud, at the. mere request (whether supported by financial. or other inducements) of the British secret Police, MI5.

And when challenged, these. broadcasters LIE about their involvement, with just as little shame as MI5 themselves. The BBCs Information. dept have said. that;

"I can. assure you that the BBC would never engage in any form of surveillance. activity such as you describe"

which is an out-and-out lie. Buerk and Lewis have. themselves lied to their colleagues in. the BBCs Information department over the "newscaster watching", but unsurprisingly they refuse to put these. denials in writing. Doubtless. if the "newscaster watching" ever comes to light, Buerk and Lewis will then continue to lie by lying about. these denials. So much for the "impartial" BBC, a nest of liars bought and. paid for by the Security. Services!

It is obvious that the persecution is at. the instigation of MI5 themselves - they have read my post, and only they. have the surveillance technology and media/political. access. Yet they have lied outright to the Security Service Tribunal. Similarly, BBC newscasters Michael Buerk. and Martyn Lewis have lied to members of. their own organisation. The continuing harassment indicates they are all petrified of. this business coming out into the open. I will continue to do everything possible. to ensure that their wrongdoing is. exposed.

MI5 Persecution Update: Friday 11. June, 1999

Harassment in a pub. in Clapham, Tuesday lunchtime

Once. a month, or once every other month, I meet a Polish friends of mine who lives in Clapham North, and. sometimes we go to a particular pub near where he lives. The. last time was some two months ago; I did not have my minidisc-walkman with me, and. consequently was seriously harassed by people. MI5 had instructed to harass me, in the pub.

This Tuesday, 8 June 1999, we again went. to the same pub for a pre-meal drink. This time I did have my minidisc-walkman with me. As. you can guess, we were followed into the pub by. a couple of young people (Im getting older and older - isnt it funny how the MI5 agents. all look young these days?). They started talking about my situation, in particular some. travel I had booked the previous day. Unfortunately, they were. talking fairly quietly, and my minidisc. didnt pick up their speech.

MI5s schizophrenic reasoning is that simultaneously I. am very important and worthy of their acts of. persecution, and I am also totally unimportant and their abuse of me "doesnt matter". Perhaps they. should test their agents and managers. for obsessive personalities or psychotic features in the same way as employees are drug-tested. MI5 might lose. their "worst cases" employees if some psychological testing. were applied to their recruitment. procedure.

Toothless Watchdogs. What a. Surprise.

Recently I have been engaging in communications with two. watchdogs, the Security Service Tribunal which deals with complaints against. the security service (and always clears MI5 of any wrongdoing), and. the Data Protection Registrar, which. is mandated to investigate misuse of personal data held on. computer.

In a letter to Nick Brooks,. Security Service Tribunal secretary, dated 20 April, I asked. him if the Tribunal, as an allegedly independent body, had the means to investigate complaints against MI5 other. than asking MI5 to themselves. investigate complaints. To my disappointment, his reply two weeks later. answered the question only indirectly, in the negative. Whatever the reader might think of the. merits of the case I have been putting before you in faxed articles this. last year and half, you will surely recognise that it is a significant anomaly. for the Tribunal to have no independent means of investigating. complaints, particularly given the view expressed even by previous home. secretaries that the security

services are. untrustworthy.

MI5. Persecution: No Justice for the Victims of MI5

In a. previous article I detailed the similarities between the current MI5 Persecution in England, and other historical instances. of similar persecution, notably that by the Nazi. Germans in the thirties and forties. The Germans. persecuted first the mentally ill, the epileptics and those suffering. from schizophrenia, then moved on to racial groups; in todays Britain the persecution is again directed. at those with mental illness, which the British in their cowardice. find easier than taking on racial. groups as the Germans did. But just as in Thirties Germany there was no recourse against a malign and omnipotent state, so. the MI5 Secret Police in the modern British. Fascist State allow no justice for their victims.

No Recourse Against. the Security Services Illegal Harassment

It has become apparent to me over. the last nine years just how loaded the dice. are in todays Britain, a fundamentally fascist country which masquerades as a democracy. Britain. is a democracy in name only; the Establishment, the defence and MI5 secret police are always. there, regardless of which party has been voted into power. most recently - and from "New Labours" conduct in office one finds it difficult. to tell them apart from Old Tories, in their crackdowns. on the sick and vulnerable in society.

In thirties Germany the. victims of the Nazi regime had no legal recourse against their State oppressors; and in todays. Fascist British state, the victims of the Establishment. and its MI5 Secret Police similarly have no recourse against the. illegal state-funded and organised oppression. There is supposed to be a mechanism for dealing with MI5. crimes, in the shape of the Security Service Tribunal and Commissioner; yet. these have never found favour of a plaintiff.. One might as well ask the Nazi SS to investigate crimes against epileptics or Jews as ask the. Security Service Tribunal to investigate MI5 crimes against British citizens; it is. quite obvious what the answer is going to be, regardless of what you say. to them, and what evidence you provide. The. Tribunal and Commissioner are a mere formality, a whitewashing body to give the Secret Services. a veneer beneath which they hide their shabby. criminality.

"Institutional Racism" and Bigotry in the Metropolitan. Police

The recent inquiry into the racist murder of Stephen Lawrence found. clear evidence of systematic and deliberate. racism in the Metropolitan Police, which cannot have surprised anyone. Commissioner. Sir Paul Condon accepted a somewhat lukewarm definition of. institutional racism as being "unconscious". In truth,. and this truth must surely be obvious to anyone who has any familiarity or encountered the. great British police, the Met has not just "unconscious" racism,. but very clearly "conscious" and deliberate. racism, of the kind that would have done Thirties Germans proud. And it. is a bastion of such open racism - when many other parts of

society are learning to live. in a multicultural environment, the Met is still living in the past in its attitude to the. minorities.

But in addition to the systematic racism. confirmed by the Lawrence inquiry, there is also something much. more relevant to this case, which is systematic police bigotry. against the physically and mentally disabled, which I personally. have experienced in my dealings with the police over the years. You cannot expect equal treatment if you. are mentally disabled. I tried to make a complaint to the police in 1995. about the harassment I had been subjected to for several years. As soon. as they found out I had mental illness, they refused to even talk to me. I. tried again in March 1999; the. police made various threats to me, while ranting about "your. paranoid rubbish" in reference to the complaints expressed to them.

The police refusal to do the job they are employed and paid to. do is extremely. serious, particularly as this case is highly important, indeed key to the whole issue of British. self-perception at the end of the 20th century and the beginning of the 21st century. Britain has. lost much in the last fifty years -. it has lost an empire, it has lost its self-respect and its identity as a people. If the MI5 persecution finally. makes it into the. light and the Security Services are seen for the rather cheap bullies their. behaviour indicates, it will have a massive and harmful effect on British self-perception in the. new century.

Security Service. Tribunal - Blatant Whitewashing

A few weeks ago I spoke on the. phone to Nick Brooks, the Secretary of the Security Service Tribunal, which is supposed to deal with cases. of MI5 transgression. I asked him if the Tribunal had ever. found in favour of a plaintiff and against the Security Service. He answered that as far as. he knew, it. had not.

I also. asked Mr Brooks if the Tribunal had any means of investigating allegations. of criminal activity by MI5, other than asking MI5 themselves if they had engaged in such activity. His rather circuitous written. reply states that the 1989 Security. Service Act provides that "it shall be the duty of every member of the Service to disclose or give to. the Tribunal such documents or information. as they may require for the purpose of enabling them to carry out their functions under this Act". Which is. a very. round-about way of saying - "No" - the Tribunal has no way of investigating MI5 crimes - None At. All.

Setting up the. S.S. Tribunal, and creating a Security Service Commissioner, was really. an act of falsehood by the government. It is generally recognised. that MI5 are out of reach of the normal criminal justice. system - the police, as we have seen, have no intesot answer to the government; in. a previous article I quoted Roy Jenkins speaking of "a secretive atmosphere.... secretive vis-a-vis the government as well. as [enemies]",. and a "lack of frankness" from MI5.

If the government wanted to, it could reform the secret services. and ensure they acted in conformance with the. laws which have been enacted for them in the last ten years. But apparently. the present government does not see any need to ensure. security service compliance with the law. As noted above, the regulatory machinery. for MI5 is deliberately weak; the Tribunal has no independent. means of investigation, and it is simply a waste of time complaining to the. Tribunal or Commissioner.

Every so often, fresh revelations come to light of. secret service transgressions. We have heard. from Shayler that MI5 bugged Jack Straw and Peter Mandelson; we have heard from Peter Wright that MI5 plotted. to see Wilson ejected from office;. yet so closed is the system of government that the. law is never enforced against MI5 when they "bug and burgle" everyone from politicians. to ordinary citizens.

No Justice from the Legal. System, either

Britain has. a civil and criminal justice system which effectively limits many complaints. from being heard. For a civil complaint to be brought before a. court, you need a solicitor willing to act on your behalf. Supposedly it. is possible to represent yourself as a Litigant-in-Pthe basis of being. "frivolous and vexatious" or "disclosing no cause for action in law". This is exactly. what happened to me in 1997 when I. twice tried to take the BBC to court for spying on me in my living room at home; my case was twice struck out, and on. the second occasion an order was made against. me that I could not bring further civil litigation against the BBC. without leave of the court.

As the reader can guess it is quite impossible for. a person with schizophrenia, who complains. about the secret services and media interfering in his life,. to find a solicitor willing to represent him in legal action against the persecutors. I have quite a. lot of evidence of the continuing persecution which I have. posted on the website, even if the evidence is quite tentative and perhaps open. to varying interpretations. But I have tried several firms of solicitors; some. of them have acted unprofessionally and. abused me; all of them have refused to represent. me. My psychiatrist gave me the name of the firm of Bindman and Partners in central London, and I. have approached them twice. On each occasion they refused to accept my instructions. Plainly the problem. with Bindmans, which they have admitted, is their. bigotry against mentally disabled people; yet this is not just something that. is wrong with Bindmans, it is something that is wrong with. the legal system as a whole, since the legal system necessitates finding a solicitor willing. to represent you in order to bring a. case to court, but it does not have a mechanism for providing a lawyer in the case where no. solicitor is willing to. take on your case. So the British legal system is such as to prevent cases such as mine from ever receiving. an airing in a court.

So much for the civil courts. But the criminal. justice system is no better. Two years ago the Protection from Harassment. Act came into force.. But again, while the Act is all very well on paper, in practice it is unenforceable in my. case, since it would require Police action to see the law implemented, and if the police cannot even be trusted to. conduct a

murder investigation competently (in the Lawrence case),. then what chance is there of. their investigating complaints against the Security Service? Of course, it. would be possible for me to personally issue proceedings. through a private prosecution either against MI5 themselves, or against one or more of their media. tools; but here we see the same problems as with the civil courts, because first. of all I would have to find a lawyer willing to act on my. behalf. Litigants-in-person do exist in the criminal courts, but the Attorney General can bring such a. prosecution to an end by taking it over and entering a plea of "nolle prossequi";. and I suspect that if I were to bring a. private prosecution against either MI5 or one of their. media tools, then this is exactly what would happen.

So much for British justice. But if anything the. wrongs that have been perpetrated on me by the British. justice system are quite mild to what others. have suffered. Others have been wrongly convicted based on police evasions and lies, and spent many years in jail based on false. charges. I should count myself lucky that. despite the best efforts of the MI5 secret police, I have not acquired any. criminal charges or convictions; which shows. that for all their resources and influence, and the clear imperfections in the British legal system, there. are still limits on how much. subversion MI5 can achieve.

The latest in. a long line of injustices

A comment I. heard during the recent scandal of the police mishandling of the Lawrence murder investigation. is that "its not as if the police themselves murdered him".. This is not a particularly wise statement to make about the case, since it. could be argued that the four alleged murderers were aided in their crime by. the expectation that the police would deliberately. botch the investigation - which of course is exactly what the police. did.

But in. my case, this would be a completely inaccurate thing to say - since the MI5 secret-police have expressly been trying to nine years now. to see an end put to my life, either by having me incarcerated and my. liberty ended, or by forcing self-termination on me. It is. exactly as if the secret police "themselves murdered. [me]", since that is what their aim is in their campaign. against me.

The public has heard of instances of. police mishandling of cases, of police manufacturing evidence, lying. in court, extracting false confessions to clear up crimes, et cetera. Various instances. of extra-legal activity by the secret services have. also come to light in the last few years. The unhappy truth. is that what MI5 have been doing to me for the last. nine years is really nothing out of the ordinary for them. To me it seems unbelievable that this sort of systematic campaign. of harassment, which thousands and thousands. of people in this country and abroad are well aware of, could exist for such a long period of time. with the media maintaining "omerta". But. my case is not the first such instance of persecution by the "British secret. police", and judging by the lack of any real controls on MI5,. I very much doubt it will be the last.

MI5 Have. Systematically Destroyed My Life

This. is getting depressing. From the feedback Ive received, the recipients of these faxes are tired of. hearing my complaints, and in truth I am tired of sending. them. The reason I havent yet ceased sending faxes is because I cannot think of any other effective means of replying. to MI5s actions against me, and. I feel I have to do something to try to defend myself. Three/four years ago I got the MI5 harassment out of. my system by posting about it on Internet newsgroups, and for a. few months this tactic was quite effective - I received. (and indeed still do today) support from newsgroup regulars, and. felt I could make my voice heard and break the MI5 monopoly on access to the. British media. But that was years ago, and today nobody gives a tinkers cuss about my. internet posts - so I have sought to escalate matters. by communicating directly with the politicians who allegedly say how this country. is supposed to be run.

Of course, its quite expensive to keep up a campaign of. fax messages for many weeks. Each set of faxes takes approx 50 hours. to send over the weekend, and. costs perhaps 35. My phone bill for the last quarter was 350. These figures are naturally insignificant compared. to what MI5 have been spending. against me over a similar period. It also takes a lot of time and energy to create a new article every. week, and try and find new and fresh aspects and viewpoints on MI5s persecution of me.. I am beginning to run out. of both new topics and energy to write these articles.

So I have a. suggestion to put before the MI5 persecutors who have been wrecking my life since 1990. In a few days time. I will be going on holiday to Poland. and Germany, for a couple of weeks. Previously, almost every time I have travelled by plane, or gone anywhere on holiday,. the MI5 "wreckers" have. been most assiduous in destroying these trips. My suggestion is; if MI5 leave me alone on this next trip, I will. cease transmitting these articles. If,. however, there are any clear instances of harassment (and I. am very capable of recognising MI5 harassment when I see it), then I will make public these instances and publish any recordings. I may make of them, and, unwillingly and. unhappily, continue the articles.

Read about the MI5 Persecution on. the Web

Keith. Hill MP (Labour - Streatham), my elected representative, as ever refuses to. help.

MI5 Refuse to Allow me to have a Normal. Life

Its kind of difficult to contemplate having a normal existence. when you know your entire house is. bugged from top to bottom, for audio and, very unpleasantly, video; when your employment. is systematically destroyed, over and over again; when every time you leave the country your travel. is disrupted by MI5 plants on the plane yelling. abuse at you..... you get the idea. I would like to have some. semblance of a normal life, like my Polish and English friends do. But MI5 have made this impossible, and they. have leached massive resources from the. taxpayer to institute a life not worthy of the. name on me.

A few years ago MI5 were very. open about their aims in persecuting me. They. were shouting "suicide" at me, both in Canada where I lived at the time, and during my. occasional visits to London. You cant get much clearer than that. There have been. instances as recently as a few weeks ago of this intention being voiced. by their side; on 15 April 1999, a woman at the next ticket counter at the. Royal Festival Hall said;

"it would kill it, you know, it would just be overkill.... they can't stop can. they"

meaning that "they". were trying to "kill it" i.e. me and they "cant stop".. The audio file is at;

I. wonder why they "cant stop". Nobody (who doesnt know already) believes my claims - so what difference would it make, if. they were to "stop". persecuting me? Perhaps what this persons remarks indicates, is the depth of the obsession MI5 have. with this case. They have chosen at random a person from the general population, and done their. worst to ruin my life. What is wrong with these people, that they persecute. a national of the country whose citizens they are supposed. to protect?

No Chance of a. Harassment-Free Job

Since the harassment started in 1990 I have had three jobs, the. first near Guildford, the second in Oxford, and the third overseas. in Canada. All three jobs have been systematically destroyed by. MI5. It is so ironic that MI5 employs a team. of agents, each well compensated for their efforts, to persecute just one person paid a mere fraction of what. they get for their "work". In fact, it is. a joke that MI5 is allocated resources for this sort of effort. If this area of government were run along. commercial lines then MI5 would be very rapidly closed down,. they produce nothing of any value, instead spending their time obsessed. with the bugging and surveillance of their former employees like. Shayler, dangerous subversives like Straw and. Mandelson, and "threats to national security" like yours truly.

Applying for my first post university. job

When I was applying for. my first post-university job in the closing months of 1990, I found at two. or three job interviews that MI5 had got there ahead of me. Interviewers knew what words to repeat from what. had been said at. my home recently; MI5 had supplied them with words to hurt me, and the "British secret police" were trying. to wreck my job search and discourage me from joining the world of work. This and. the continuing

harassment in the media and by the public meant that the. search for a job took very much longer than it would ordinarily. be expected to take for a person with. my qualifications.

With my. first job near Guildford came the knowledge that MI5 were doing everything possible to. make me lose the job. Despite their efforts I managed to stay in. work for ten unhappy months, during which they made very. clear to me that they were bugging my workplace, my accomodation in Woking, my car, my home..... and they also made. clear that they had "got to" my employer. in Guildford.

Employment with. Oxford

I was able to find a new job,. with Oxford Computer Training Services (now ARIS/Oxford), quite. quickly. But it became very clear, very quickly, that MI5. were treating this job the same as the first; they tried to get the other employees and. in particular the managers to attack me. It was plainly. MI5s intention that I be sacked fro this job. But I was not sacked; instead,. after almost a year of abuse from OCTS managers, I was forced to. seek medical help, and had to take two months off for medical leave. OCTS MD Hugh Simpson-Wells was motivated in. keeping me on by the fear that if. he sacked me, then I would take him to court for the treatment OCTS managers had meted out to me. during 1992.

Emigration. to Canada

When I emigrated. to Canada in 1994, I did think that perhaps MI5 would leave me alone, given that I had made the effort to leave the. UK and try to find a new life overseas. I could not see. any reason why they would continue to harass. me over in Canada. But clearly the MI5 agents had their salaries to think. about, since continue to harass me they most certainly did, at my home in. Ottawa, and by getting fellow employees to speak against me, as had happened with. previous jobs in the UK.

MI5 are denying me a. future in work

Former Chief Constable of Devon and Cornwall John Alderson had this to. say regarding. MI5's activities;

"MI5 is not under the same restraints as. the police. They infiltrate organisations, people's. jobs and lives. They operate almost like a cancer."

Currently I am on disability, and I can. see that MI5 are denying me a future in work. It. would be an insult to logic for me to return to work and find a job, in the. knowledge that an entire team of MI5 agents, paid in total many times what I would be earning, would. have the objective of seeing me "done down". in the employment, and ejected from the place of work. This situation is completely wrong and nonsensical -. I would very much like to have a job, but MI5. are preventing me from even thinking about returning to work. The culture of secrecy in MI5/MI6 means. there is no objective oversight of their expenditure, when external. oversight and greater transparency might lead to wasteful. and illogical operations such

as that. against me being shelved.

Watched and Harassed at. my Home and Accommodation

As you will know if you have been reading these articles, MI5. have watched and harassed me at my home, and at every. accommodation Ive had since 1990. Theyve also watched me at neighbours. houses in London, and at short-term accommodation such. as hotels and bed-and-breakfasts. They have used the "words" gained from these watching activities against me,. by passing these words on to other people such. as OCTS managers for them to make clear that I am. being watched where I live.

Harassed at. rented rooms in Oxford in 1992

This was at its worst in 1992 in Oxford, where during the week. I lived at rented accommodation in Oxford, and at weekends returned to. my parents home in London. I was being. severely harassed by managers at my place of work, OCTS; and it. was clear from the things they said that they were being supplied by MI5 with details of my home life, that they were. being supplied. with words to repeat at me.

In 1992 I moved house in Oxford many. times, living at a total of five rented accommodations in ten months. In January. I started off living in a rented room at Headington near the ring road. / A40 intersection; then when it became clear that house was being bugged, moved to a rented room. in Botley, some miles away. It was at the house in Botley that I had. an "interactive. watching" experience with Martyn Lewis while he was reading the news; I threw a term. of abuse at him; he first flinched, then gave a gsult. of what I had just said, he was no longer "on my side".

So I moved house again. This time to a place in Cowley, near the. Rover car works, where I stayed for a few weeks. Because of continuing. harassment at work, I soon moved from this accommodation, to. yet another rented room on Iffley Road. By this time I was very ill and being abused continuously. at work. Again, MI5 followed me to the rented room on. Iffley Road, and created new instances of "newscaster. watching". There was a television in the room which I watched, and as you can guess the newscasters got at. me when. I was watching the television. Also once I was assaulted, if thats the word for what happened, on leaving the house; a. youth grabbed me by the coat lapels, roughed me up a bit with various terms of abuse.. I did not report this assault to the police, because what was happening to. me at work was very much worse,. and nobody seemed to think that that was worthy of being reported to the police.. Later that day at work, Alex G, a fellow employee, said "I. heard he was assaulted".... I had not told anyone at work about the incident that morning..... so once. again it was made very clear that MI5 were watching my rented. accommodation and giving information about what was going on there to managers at. work.

So I moved house yet again in late autumn 1992,. this time to a rented room in a large house on Woodstock Road.. I stayed there for several weeks as the situation at work deteriorated due to OCTS managers. abuse, until I was forced to take. sick leave from work for two months and attend hospital as

an outpatient;. at which point I gave notice on the room, and returned to London.

MI5 continued to harass me after. the diagnosis of serious illness was made.. As reported previously, they harassed me on a flight to Spain in December 1992; and in 1993, when I returned to. live and work in Oxford, they again bugged my rooms, as well as my workplace,. although the intensity of the harassment was very. much less than in 1992.

Watched, followed. and harassed in Canada

It dismayed me to find that MI5 would. not leave me alone after I had settled in Canada. In January 1995 I rented an apartment at. the Bayshore complex in Ottawas west end. For. some weeks there was no sign of the "buggers".. But then it started all over again. They first bugged my car, which had a car alarm installed - the alarm went off two. or three times in a single evening, and. the following day gave a signal that the car had been broken into.. Then they bugged my apartment, and in particular they installed bugs on the phone. line in my apartment.

In September 1995 I moved to a new apartment in. Ottawas Bytown Market area, the restaurant. and entertainment heart of Canadas capital. This proved a serious mistake. In the west. end I had been fairly distant from the centre of town where MI5 concentrated their efforts at turning. people against me. In the Market area it was much easier for the persecutors. to motivate people to harass me, and over the next couple of. years there were frequent instances of harassment by the. general public.

From 1995 I had some. Polish friends in Ottawa, and as the reader can guess, MI5 have spent much effort. trying to break up this friendship. They supplied various things about my home life to these friends, for. example where I was living in the Market, directly over the road. were the studios of a music radio station, which you had to "look up" to. see; and MI5 told these. friends that I was "looking up" to see the radio station; so the friends then replayed these words back to me, that I was "looking up".. MI5 have also made various sexual slanders. against me, and these friends also unwittingly replayed some of the words they had been. imprinted with by the MI5. persecutors.

MI5 Will Never Allow Me to. have a Normal Life

I have heard many. excuses as to why MI5 continuously prevent me from having. a normal life. We are told that MI5 are defending the country against a. tere to zero.

When I have travelled abroad, they always put their people on. the flights, on the journeys I undertake, to. continue the harassment, so that I am put off. further overseas travel, and chained to my home in London. Yet even this is. illogical, because when I lived in Canada, they would still put people on flights. back to the UK.... and what possible reason would they have for. doing that? Perhaps the truest words to describe the MI5 persecution. is that reason has nothing to do with their activities - sane people do not behave in the way. the MI5 British Secret Police have been

doing.

Summer 1999 -. more MI5 harassment?

In only a few days time I will. be going to Europe again. This time I have deliberately chosen to travel by a non-UK airline; so we will. see if they put their paid agents on this foreign carrier,. we will see if they try to harass me on this non-British. flight.

If they. do harass me on this trip to Europe, or if they resume the harassment in London after I return home, then I. will continue to report their activities in these faxes. As. I said at the beginning of this article, I would very much like to not. have to send these articles any more, but that is not my decision to make - it is entirely up to MI5. to cease their pointless persecution of me,. once and for all.

MI5 Persecution Update:. Friday 9 July, 1999

Harassment in. Poland, July 1999

And still it continues.... in. my last fax I said that provided MI5 made no attempts at harassment during my two-week holiday this summer,. or after I returned to England, then I would discontinue these. faxes. Unfortunately MI5 have continued to harass me, both during the holiday. and after my return to London. I really dont want to continue these. articles, since they take up so much time and effort, not. to mention expense; but the Security Service wont. even let me have a holiday in peace and quiet, so I have to make further efforts to bring their activities out. into the open.

In early July I visited my aunt. and her family in Poland. On Saturday 3 July 1999, I went to a family barbecue. at an allotment outside the city. One of my aunts family has previously shown himself. to be in the "enemy" camp, by saying the Polish equivalent of. "something wrong with him", and various other unprovoked. insults. It is disappointing that one of my family could forsake the usual ties of blood and take part in. the actions against me, but thats the way it is.. This guy turned up at the barbecue, and started making insults against me. In. particular, he started to say something about the video camera which I had brought along on. the trip, and the relevance. of the video-camera to my fight against the persecution. It seemed pretty obvious. to me that my enemies had told him to turn. up to this occasion, and most likely schooled him in precisely what words to say; since hes an unintelligent person. and would not be able to. think for himself what insults to make against me.

Harassment in London, week ending. Friday 9 July 1999

Got back to London Wednesay afternoon.. Two incidents on the Underground returning from the airport. Unfortunately I wasnt recording. because I wasnt expecting trouble, so these slipped. through the net. One of these was verbal sexual abuse, of. the type Ive heard many, many times before these last. three-and-a-half years.

Yesterday, Thursday 8/July/1999, I switched on Heart. FM which had never "got at" me before.... and the. presenter started making jokes about "mad, crazy" etc. Again,. wasnt recording this because Id never had any trouble from this radio. station and wasnt expecting any.

Also yesterday, on a bus (155?) from Balham to Clapham,. a couple of girls started harassing me with taunts of. "crazy". By now I was expecting trouble and recorded an audio file. of this instance of abuse, at web URL;

The cynical reader might think my. demeanour or behaviour had given rise to the. taunts of "crazy" recorded above. But I assure you my behaviour on the bus would not have made. anyone think I was ill; and the taunts the previous day were the same. sexual words as previously; so I'm quite sure that these incidents are either deliberately staged, or. indicative of an overall high level of awareness among the. London public, particularly in the part. of London where I live.

Keith Hill MP (Labour - Streatham), my. elected representative, as ever refuses to. help.

MI5 Persecution: Harassment through. the Radio

One of the aspects. of the MI5 persecution has been harassment through the broadcast and print media; and one of the aspects. of harassment through the broadcast media is being "got. at" by radio presenters. This being "got at" from the radio takes various. forms, the most obvious form being through overt or hidden words and insults.. But there are other, subtler forms. In Canada a couple of years. ago, I used to listen to the local radio stations every morning driving to work, and listened to. the music only, switching between radio station presets rapidly. as soon as a presenters. voice came on, so that I would not be subjected to any verbal harassment by the D.J.s. But they. found a way around this; they kept on playing the same song, every bl**dy morning at the same. time, which had the words "all. coming back to me"; the perceptive reader will remember that. the words "coming back" have special meaning (see the Private Eye cover. at web URL; for the
hidden. meaning).

And thats not the only time theyve allowed the songs themselves to. be used as abuse against me; many years ago Radio-1 in the UK. did exactly the same, and the DJ even made it explicitly clear. by saying, "dont you sometimes feel as if the songs were made. just for you".

"We should be done for attempted manslaughter". says Chris Tarrant

Capital Radio DJs have been "in on it". from the start. One of the first things I heard in the summer of 1990. was from a Capital DJ who said, "If he listens to Capital then he. can't be all bad" (supportive, you see. We're not bastards). Much of what came over. the radio in 1990 is now so far away the. precise details have been obliterated by time. No diary was kept of the details,. and although archives if they exist may give pointers,. the ambiguity of what broadcasters said would leave that open to re-interpretation.

In spring 1994, Chris Tarrant on his Capital morning show. made an aside to someone else in the. studio, about a person he didn't identify. He said, "You know this bloke? He says we're trying to kill him. We should. be done for attempted. manslaughter".

That mirrored something I had said. a day or two before. What Tarrant said was understood by the staff member in the studio he. was saying it to; they said, "Oh no, don't say. that" to Tarrant. If any archives exist of the morning show (probably unlikely) then it could be. found there; what he

said was. so out of context that he would be very hard put to find an explanation. A couple of days later, someone at the site where I. was working repeated the remark although in a different. way; they said there had been people in a computer room when automatic fire extinguishers. went off and those people were. "thinking of suing for attempted manslaughter".

Pirate Radio "gets at". me

In another incident in 1990/91, Id been listening. to a pirate radio station in South London for half. an hour, when there was an audible phone call in the background, then total silence. for a few moments, followed by shrieks of laughter. "So what are we supposed. to say now? Deadly torture? Hes. going to talk to us now, isnt he?" which meant that they could hear. what I would say in my room. Note the word "deadly" - they give away. their purpose.

It constantly surprised me that MI5 are so. easily able to subvert broadcasters, and, in this case. of the pirate station, to do so, so quickly. I think the answer to this question is that they. must have very wide contacts in. the broadcast media; presumably some or in fact many of those contacts are literally. "bought". In the same way as they tried to buy Jon Snow of Channel Four news, they must. have bought many broadcasters and use them both directly to make insults against. me, and promulgate their points of. view; but also, they must use these "bought" broadcasters to influence other television and radio presenters, who might not even. be aware that it was on MI5s behalf that. they were being influenced to "get at". me.

BBC-Radio-1 D.J.s celebrate. my job termination in November 1991

This is another one from the "early years".. At the beginning of November 1991 my employment. in Woking, Surrey was terminated. Chris Tarrant of Capital-FM had already made nasty remarks about both. my work for the company, and the managers of the company themselves. - "so theyre not really a serious company,. well theyd have to be to employ you wouldnt they".

So when I was terminated, as you can expect,. BBC Radio 1 D.J.s celebrated. On the Saturday afternoon (either 9/Nov/1991 or. 16/Nov/1991 - I cannot remember precisely) I. briefly listened to Radio-1 and heard the disc jockeys loudly proclaiming "youre useless,. you should be sacked". On the same day, I went down to the Kwik-Fit in Tooting to get. my cars tyres replaced, and in the office ran into a couple of. their staff, one of them with an Australian. accent, who said "what do you think about it then? Its getting killed on the. radio."

Plainly, if a random car-repair. shop in Tooting knew about the persecution, then many thousands of other people across the capital. and all over the country must have known.. And the phrase "getting killed" shows very clear awareness of what the. MI5 Persecutors intentions towards me were in 1991, and judging by the continuing harassment,. still remain. today.

Recent. Feedback from Virgin-Radio

As readers will know,. from mid-March 1999 for some four months, every weekend, I have. bombarded Westminster MPs with faxes about the terrible, all-encompassing MI5 Persecution. (Jesting aside, it. really is terrible and all-encompassing, in the UK anyway.) In. June 1999, after I'd been at it some three months, I started. getting "covert" feedback from Virgin Radio.

The first feedback I. got was from Danny Baker, on Sunday 13th June. That weekend I was sending an article which contained biting. criticism of the police inaction in. this case. Danny Baker on his Virgin radio show started an angry rant that "he knows. it's rubbish", ie. he was rubbishing what I'd said in that weekend's faxed article.. Unfortunately I wasn't recording this. programme.

The next possible Virgin-Radio feedback was a week. later on 19th June 1999. This is contained in the audio file above, in. which Johnny Boy on his "Wheels of Steel". programme says;

"and if you would like to. put a triple play together, ahhh.... because quite frankly Hipster and me are running. out of ideas...."

He goes. on to counter Hipster's "how dare you" with a protestation that he is "only joking".. You can listen to this incident on my website at URL;

What I reckon is that my article faxed to MPs that. weekend was forwarded by one of. the recipients to Virgin Radio. My article had included the words;

"I am beginning to. run out of both new topics and energy to write these articles."

So what I reckon is that Johnny. Boy read the article.... and rephrased the above line "run. out of ... new topics" to "running out of ideas". I recognise that this is a pretty tenuous inference to make..... but do listen to the audio file, from the "ahhh...." pause in. JB's speech you can guess he is. about to say something "risky" and at someone's expense. Anyway, I listen to the Wheels. of Steel regularly and will continue to do so, recording. it as I always do - so any future funny remarks will. get immortalised on my website! (There was a previous incident from August. 1998 which is preserved at web URL;

but I. am sufficiently uncertain about it that I have not included it in this. article.)

First Ever Radio Reference - Alan Freeman of. BBC-Radio-1

The first time I was ever referred. to on the radio was sometime in May or June of 1990, by Alan Freeman of BBC-Radio-1. Note that. this isnt an "interactive listening" episode,. its different, this was Freeman reading out. a letter from one of my "real life" enemies.

Id acrimoniously broken up. with some former friends in January of 1990, and I think they were still trying to cause me trouble in June of. that

year. Freeman on his rock show read. out a letter from an "Andrew Turner"; one of my acquaintances from January. 1990 had been called Andy Turner,. so I think its the same guy. Freeman quoted Turner as saying various things about me, in particular Freeman said "thats a. hell of a letter. you wrote there Andy", "with a schizophrenic you're never alone", and something about the. "one who wore out his welcome with random precision". (from the words of the Pink Floyd song).

When I. was looking for primary causes of the MI5 persecution, this letter which Freeman had read out on his programme struck me as. being potentially one of the sources of the persecution. I know Turner and various. others in that group. were very bitter at what they saw as their failure and my undeserved success, and they were quite determined to upset. the applecart. Of course several other primary causes are. possible; I do not know why MI5 chose me as opposed. to someone else, and MI5 are hardly likely to. tell me.

"Absolute Obscene" David Hepworth. of GLR

This one Ive assigned a 100% rating on the. website. There are actually two separate incidents, which are linked. through the D.J.s choice of words. The first incident can be heard in computer. audio at web URL;

On 21/Feb/1997, I was listening. to BBC GLR, by stealth. Back in 1990 I used to have Capital blaring out. of the speakers all over the garden ("if he listens to Capital then he can't be all bad",. thanks ever so much). But now I listen on my. walkman on headphones with the volume turned right down. It could not possibly be overheard. by any listening device, no matter how sensitive, because sound does not. carry from the phones.

Yet somehow they are still able. to tell which station I am listening to on the walkman. And last night, I bravely tuned to. GLR 94.9FM at around 8.45pm. Everything. went well for the first half hour or so. Around 9.10pm, Hepworth. said the following after the song "Come Around" by the Muttonbirds.

"coming up after this, we got the. rock-and-roll A-level, we have, I assume,. Brian do we have an embarrassment of prizes in there, we do, don't we, absolute obscene amounts of prizes,. there will no doubt be a riot at the. back door, and that's, er, A-level coming up after this"

The key phrases in what he said are,. "EMBARRASSMENT of prizes", and what he himself emphasized verbally, "ABSOLUTE OBSCENE amount. of prizes". It is my belief (based. on content and tone of voice) that when he spoke these phrases he. knew I was listening, and that the phrases refer directly to my situation. The "EMBARRASSMENT" is the embarrassment. he and other media people would. feel at having their wrongdoing exposed; the "ABSOLUTE OBSCENE" (which. he verbally emphasized) described the disgusting sexual abuse which the harassers have been throwing. at me.

There was a second incident, on 9/May/1997, which. may be found on the web (with. computer audio) at URL;

This incident again contains the words. "absolute embarrassment of prizes", with the same emphasis as the first instance, and laughter. following the phrase. So theyre aware. of the complaint I made on Usenet after the first incident; and they are so arrogant that they do. exactly the same again. They are so arrogant, they know they are being. recorded and that what they say will be. published on the web, but they dont care. What corrupt media, and what a corrupt country to have such corruption in. its media.

Three Years of "MI5 Persecution". Faxes

Ten Thousand Faxes,. and Still No Breakthrough

In the last three years I. have sent at least 5,301 faxes directly from my computer,. and 4,478 faxes through Demons extremely useful TPC.INT service, to politicians and the. media, in the subject of the "MI5 Persecution". This has. obviously cost me quite a lot of money, not to mention time and effort. The aim of all this communication has been to. try to put discussion of the "MI5 persecution". into the public arena; unfortunately,. this aim has not been achieved, yet.

This fax will be. my last transmission for the time being, since the summer recess is almost upon us. Depending on what the persecutors do between. now and the autumn, I may or may not resume faxing later. this year. In the article dated 18/6/99 I said Id stop the articles if. MI5 left me alone; but they seem to have. no fear of these articles, since they kept pursuing me in Poland and after my return to the. UK. Again, if they leave me alone this summer. then I wont have to resume the articles in the autumn; but I think its fairly obvious that MI5. have nothing better to do with their time than to go after. me, and its almost pointless to make this offer when I know they wont cease harassing. me.

TPC.INT 1996,. 1997, 1998.....

Three years ago I was. living in Canada, and the only economic way of sending. faxes to the UK was through the international email-to-fax gateway TPC.INT. This highly useful and totally free service converts. emails (which. may have Postscript-formatted attachments) into faxes which it delivers to any number within the UK. Using. the telephone book, I constructed a computer. database of M.P.s fax numbers, and used this database to deliver copies of. the "FAQ - frequently asked questions" article which Id. written some time earlier.

This service. is still operational, but given that I have resided in London for. the last year, I do not need to use Demons service when I can send articles directly from my own computer using its fax/modem, which. is what I. have been doing since 1998. However, instead of just sending the FAQ article, Ive been composing. articles on various aspects of MI5s treatment of me. Since their activities have been going. on for nine years now, and there have been various aspects to their actions; they have harassed me. at work, at. home, through the media, etc; I have so far not run out of things to say,. particularly since their harassment of me is still ongoing, and I have been able to record. the actual words used by their paid agents on my

minidisc-walkman. Since mid-March 1999 I have been sending these. articles pretty much. every weekend.

Anyway, as mentioned. above, I intend this to be the final transmission before the summer recess,. and it would be nice not to have to continue these. articles in the autumn. But thats something that depends on them, not me, and their attitude. is unfortunately clear.

Why am I sending these. articles?

Because I want the harassment to stop.. The cynical reader might think from these articles that I "thrive on adversity" and would be lost without. the harassment to complain about; but that is not the. case. In a perfect world I would like to return to work, in a job unsullied by MI5s attempts. to ruin it; I would. like to live in a house which wasnt bugged, with my words being repeated at. me wherever I go; I would like a normal life. I do not particularly thrive on adversity; I am beaten. down by adversity; the purpose of these faxes. is to try to bring the whole matter out into the public arena, where the rights and wrongs would be visible to. all, and once that were to happen, the adversity might. cease. I have had something approaching a normal life. a couple of times in the last nine years, but always, in the end, MI5 turn up and ruin it. I just want these people. out of my life, permanently, and the only. way of doing that is to kick this business into the public arena, and shame MI5 so that they are. incapable of. doing me further damage.

Having. said that, unfortunately it seems fairly obvious by now that these faxed articles are. not going to achieve that aim. Some of the recipients know what I am saying is true; but they choose. to stay quiet - wisely, because if they were to admit the truth. of these articles, then they would bring the wrath of MI5 down on their heads. Presumably. most recipients do not know these articles are. true; their reaction to me is the same as my reaction to. the other apparently deluded people who have sent me email after reading my webpage to. tell me it happened to them too; the reaction being, "leave me alone, I dont want to. know". Its sad that many M.P.s have given me this reaction, because my case genuinely is. different; I genuinely am telling the truth, and the harassment genuinely is. happening to me, and some recipients of this fax know. this to be true.

"Write to. your own M.P."

My local M.P. is. Mr Keith Hill, Labour-Streatham. He refuses to have anything to do with me. He. refuses to represent me, he refuses to talk to me, he has told. me not to communicate with him. He has done absolutely nothing to help me,. and he has told me he will do absolutely nothing to help. me.

Other M.P.s, recipients of these faxes, have for quite some. time been telling me, "write. to your own M.P.". On 23 March 1998, Paul Burstow M.P. wrote to me; "Whilst I. take the issues that you raise seriously, there is a strict Parliamentary convention that. one Member of Parliament does. not take up anothers casework. Can I suggest that you write to your

own M.P. at the House. of Commons?" Hopefully the above paragraph will make clear that I have written. to my own M.P. and he has proved unhelpful.

Other M.P.s have told me the same thing. On 21. May 1998, John McFall M.P. told me, "... there is a parliamentary. convention that M.P.s do not take up cases of people not in. their constituency..... therefore can I suggest that you write to your local M.P. who. will be better able to assist you." And on 8 June. 1998, Michael Foster M.P. wrote to me that "M.P.s are inundated with. unsolicited faxes .... M.P.s have a considerable amount of constituent work to. deal with, thus other M.P.s constituents cease to be of. concern in so far as they should have a voice and representation".

Simon Hughes. M.P. wrote to me on 5 November 1998, "There is a strict parliamentary convention which states. that I am not able to represent individuals who are not constituents of mine. My advice. is that you find out who your. own Member of Parliament is rather than circulating your story to all M.P.s.". To my suggestion that Keith Hill M.P.. was doing nothing to help me, George Foulkes M.P. sent the following. faxed response;. "If Keith Hill your own M.P. cannot help no-one else in the House of Commons can.". But it is clearly not a case of "cannot" help, but "will not" help. I have detailed in letters to. Mr Hill specific ways in which he could help me, first of all by finding a lawyer. to represent me. It is Mr. Hills job as a Member of Parliament to represent his constituents; if he chooses not to do so, then. it reflects badly on him.

Kate Hoey Sympathises, but says, "Write to your own. M.P."

Here is. part of a letter Ms Hoey sent to me on 15 June 1999.

I appreciate that you have concerns about. the persecution and harassment that you feel you are experiencing but I note that. your MP is in fact Keith Hill. There is a very strict Parliamentary. code which means that M.P.s can only take action on matters that relate to. their own constituents.. I am aware that you are not happy with the fact that you do not feel Mr Hill will assist. you but I am afraid that I cannot take any action. on your behalf.

Ms Hoey plainly belongs in the. camp of people who do not know about the reality of the "MI5 Persecution". She doubts its existence;. "the harassment you. feel you are experiencing". She urges me to see Mr Hills assistance, as have other M.P.s. detailed above.

Really, the fact that I am unable to. obtain assistance from any other M.P., if my own alleged. "representative" Mr Hill chooses not to represent me, is a very. basic weakness in the Parliamentary system. Beinggmainly events at my former employers in Oxford. during 1992, when I was harassed constantly by manager Steve Mitchell for most of. 1992, and was forced to begin attending hospital as an outpatient as a result. This. harassment was obviously of Mitchells own volition, since I observed. him harass similarly another new worker. two years later; but it was also at MI5s instigation, since they kept providing him. with words from my home life which he then

proceeded to abuse me with. Yet this. is not the only employment that MI5 have destroyed; the MI5 persecution has. lasted from the end of my student days until. the present time, during which I have had three jobs, all of which have. been in various ways destroyed by MI5s deliberate actions.

In March 1999 I decided to. try to force the issue once and for all. Ever weekend for the last four months, apart from two. weeks when I was on holiday, I have. sent original articles by fax directly from my computer to Westminster politicians. Here. is a summary of the articles of the last four. months;

How to. Identify the Persecutors

Their use of Schizophrenia to discredit my. claims
Comparing the MI5 Persecution with German "Final. Solution"
MI5 are Plainly. Trying to Kill Me
MI5 Waste Taxpayer Millions. on Pointless Hate-Campaign
Four Years of. "MI5 Persecution" Posts on Internet Newsgroups
MI5 Agents are Clinical. Psychopaths
BBC Newscasters Lior the Victims. of MI5
MI5 Have Systematically Destroyed. My Life
Harassment through the. Radio

To my deep worry. these fourteen faxed articles have still not achieved the objective of kicking the matter. out into the public arena and forcing an admission either from the persecutors,. or from those "in the know", which includes. some M.P.s.

I dont really know what else to do to try to bring. the "MI5 persecution" out into the open. I would have expected. that these weekly faxed articles would have had some. effect, but the only result has been M.P.s telling me to contact my own. representative Mr Hill who refuses to talk to me. I. understand the convention that M.P.s deal with their own constituents and not those of other M.P.s, but there seems to. be a gap in the process since it allows your own M.P. to refuse. to deal with you, and then you are. totally denied any representation at all.

Conclusion

The only conclusion I can inform the readership of these articles of,. is that there. is no conclusion to this matter, yet! Three years of intermittent articles, and four months of faxes every weekend, have. been absorbed by some of the most powerful people in the country, to no. effect.

Whether these articles continue in the Autumn is entirely. up to the "opposition". I offered them a cessation. of complaints if they would leave me alone on holiday in June/July, and they went right. ahead and harassed me anyway, on holiday and after I. returned to London. If MI5 cease their activities now, then I wont have to continue these. faxes in the autumn; but I suspect they wont cease, which means. youre in for more articles later. this year. "There will be no conclusion."

Dear Rich

Thanks very much!! Gave me a lot of things to study n try

Happy new years

I didn't have any roof ground options did in my apt, my first
experiment was to put the antenna on a test rig(817) by itself on
battery same exact problem

disconnecting the ant at roof kills the noise so i presume most if
it is picked up via antenna not sure if this was scientific seems
true thou

Getting inside that room thou or once inside the cabnets might prove
difficult the building considers the new work up there as sacrade
grounds now they didn't even paint the room, and can't figure this
one out, took out the 120v outlet that used to be on the wall for
service not even sure thats legal (code) but certainly inconvient

so what i saw from looking in the window didn't tell me anything about
grounds but an execellent idea i overlooked, i can see their
cabinets are connected via metal conduit so i presume there is some
ground made couldn't tell of the motors the wires are in a conduit
that seems to go tothe motor so i can't see any actual connections

i was always guessing it wasn't the motor since the noise will occur
even if the motor isn't turning however i understand now that it could
be either an antenna or energized during it's still moments

the motors are closest to my antena and the cabinets are furthest and
at right angles perp however the entire room is only 15x15

i just can't figure why the noise isn't constant thou or exactly
intermittant ie it can be on 3 off 2 on 4 off 7

thanks very much Rich!!

MI5 Want Me. to Send You these Faxes

MI5 seem to Want to Spin this Business. out for as Long as Possible

The MI5 persecution. has now been going on, starting from June 1990, for well over nine years. If I knew how to put an end to it then I would. do so. Of course MI5 have indicated how they wish. to finish the matter, by finishing me off; they indicated this very clearly years ago when. they were shouting "suicide". at me.

But a deeper truth is that the MI5 agents carrying out the. persecution rely on it for their income and their livelihood.. They have absolutely no interest in anything other than spinning. out the whole business, because that is how. they will maximise their earnings from their employer for the "work" they do against. me.

A vital part of the fantasy structure MI5 have created about me is. that I am somehow a worthwhile target. If you bother to read these faxes,. if you browse my website, or perhaps read my. posts on the uk.misc newsgroup, you will have by now twigged that I am. a totally insignificant person who in a proper dictatorship like. East Germany would not merit five minutes of Stasi time.. But Britain is improper in the methods of its corruption, and the Security Service seeks to present me as. being a an evil fascist, an evil communist, an evil something-else, and even a. "national institution".

It. occurs to me that to some extent I am playing into their hands, into their scheme. of things, by writing these articles and sending these faxes. By doing these things, I elevate. my profile, and fuel MI5s paranoid obsession with me. But to stop sending faxes would be to give. up the only hope. I have of seeing their campaign "outed" and justice done. Certainly there is. no point going to the police again; and as remarked in a previous article,. the Security Service Tribunal routinely whitewashes every complaint that is. placed before it.

So although MI5 seems to want me to continue. sending these faxes, doing this is the only real chance. of getting this business out into the open. And so Ill continue. trying to kick down their house of cards. At least. my situation is less serious than that of some other victims of the secret services; unlike Shayler I. am not broke and exiled; unlike Fayed I have not lost a son to the posited activities of the secret. services. All I have lost is some of my health, some of my life, and some of. my possible career.

MI5s Abuse of me is without Cause or. Reason

It constantly puzzles. me that MI5 refuse to leave me alone, wherever I go and whatever. I do, or rather, whatever I dont do, since Im not a very socially or otherwise. active person. When I am in England, they chase me all. over the place, and once theyve found me, they pay people to shout rude words at me. When I am in Europe, they. again chase me all over the place, and as usual pay people. to shout obscenities at me. When I am in Canada or visiting the States, they faithfully chase me all. over the place, and when they find me, pay people to shout obscenities at. me.

It is hard to avoid the conclusion that these. MI5 operatives who chase me are total lunatics. You will remember from a previous articles. the assessment "MI5 Agents. are Clinical Psychopaths". They have tried to blame me for what they do and what they say; yet their lies have. been wafer-thin,. and are clearly seen to be oiled by the money which they acquire from. the Government, and ultimately from the taxpayer.

They have tried various lies to put the. blame on me; "we have to abuse him because hes a nutter", as if there werent many tens. of thousands of other people with schizophrenia in the United Kingdom. Their choice. of abuse words is telling; subconsciously perhaps they realise. that it is they who are the "nutters", and they try to. project their own illness onto their target.

MI5 Operatives have Nothing Else to. Do With Their Time

Ive seen the same "Alan Holdsworth" person three or. four times over a period of several years. I saw him at the Civic Hospital in. Ottawa in the Emergency Ward, where he falsely declared his. name to be "Tad"; at Ottawa airport in. summer 1998; and on board another flight in 1995.

So what we see from the. above paragraph is, the same people are delegated to watch me for many years. Without me, they wouldnt. have a job. They literally have. nothing else to do with their time, except indulge their voyeurism against me. With. this observation, we come to the core of MI5s campaign against. me; these people are not fit for any job other than the exercise of voyeurism against. me, and if sanity were to land on MI5 then they would be out of a job.. If sanity were truly to land then these people and their employers would be prosecuted. for offences under the Protection from Harassment legislation, which. they are clearly breaking.

It is one of the ironies. of their campaign that MI5 have been trying to make me an object of ridicule for. completely trivial things I have done, while MI5 themselves have simply not mentioned how ridiculous is their. own behaviour and that of broadcast media journalists, in spying on me. while they read the news for example. If the. whole truth of this business is ever. exposed, and despite all my efforts it still seems there is a block on its exposure in Britain,. then the rights and wrongs will be clear to all, and no amount of MI5 lies will be able to change that.. MI5 presumably do realise just how damaging such a revelation would. be both to themselves, and to broadcast media such as. the BBC and ITN, because there has not. been even the slightest chink in the armour, despite four and a half. years of my complaints on internet newsgroups and by fax to politicians. and the media.

MI5s Final Kick. in the Teeth to the British State

For someone like myself born in the late. sixties it seems peculiar to think that Great Britain once used to have a. say in the destiny of foreign peoples in far-off sections of the globe. Modern. Britons tacitly accept the lowering of their country to a. third-rate power reliant on the United States for what little say it has in the world. A third-rate. power, now "reverse-colonised". by third world peoples it once ruled and riven with internal problems so severe. the government hardly dares acknowledge them.

To this third-rate power. the MI5 secret police are delivering the final kick in the teeth through a campaign of persecution which is guaranteed. to hold. the state up to ridicule throughout the world when it is finally exposed. As a "thought experiment" suppose. the French or the Spanish security service had done to one of their own born citizens what MI5. has done. in this country. Suppose say the Spanish had planted hidden cameras in his home, for the perverted pleasure. of their state television newscasters, just. as hidden cameras have been placed in my home for the perverted pleasure of Martyn Lewis,. Nicholas Witchell et al. Suppose the Spanish service had for. nine years been trying to force suicide on their target; at times, so blatantly that they. shouted the word "suicide".

Now suppose. they were caught.

Of course, as long as MI5 arent caught, theyre laughing. The. psychopathic security service agents. gets their kicks from shouting abuse at me; the newscasters,. Lewis, Witchell etc get their jollies, "it was so funny", we were watching this bloke and he. couldnt do anything about it.

But once theyre caught, the sky falls. in. Of course, the "patriotic" MI5-funded media in. Britain will try to put the best spin on the. MI5/media activities; it was the targets fault, of course. But most of the world bears no allegiance to. Britain. If this business is ever exposed then a weakened. Britain will become the laughing-stock of the world. And I promise you, the security services persecution of me will be exposed.. MI5 has. delivered a final kick in the teeth to the British state, and I will do everything I can to ensure the world hears. about what they have done.

Metropolitan Police Refuse to. Investigate the MI5 persecution

I have on a. couple of occasions tried to motivate the police to investigate MI5s actions against me. On each occasion. they have refused to do. so. In 1995 I went to my local police station and spoke to an officer there;. he refused to accept my complaint, and seemed interested only in seeing me leave the. station as quickly as possible.

Earlier this year I. had some communications with Det.Sgt.Richards of Charing Cross. police. Again I asked him to deal with MI5s actions against me. Unfortunately DS Richards conformed. to the negative stereotype of the bigoted, ignorant "copper"; he. said, "I have read your various bits on the internet.. I'm afraid there is no substance or credence to it. It's an absolute load of rubbish. I don't investigate. rubbish. I can't be more blunt or to the point. than that."

You have to wonder at the state. of law enforcement in Britain. If the victim of a murder. is black, as happened in the Lawrence case, the police deliberately botch the investigation. If. the victim of a crime is mentally ill, and the perpetrators are the secret services, as. in my case, then the police refuse to even begin to investigate the. crimes committed. Politically Britain is a third-rate country,. but from the point of view of obtaining justice, Britain. ranks down there with third-world countries. You almost. feel that MI5 and their media buddies would not even have any shame if. their activities against me were exposed; after all, why should they? they have the. money, they have the control, OK so perhaps theyve broken a few dozen laws, but doesnt the. fact that the police are too corrupt to investigate these crimes, doesnt that prove that in. fact no crimes. have been committed?

I. should say again what I have said earlier in this article. My losses over the last nine years have. not been as great as those of other victims of British Secret Police malefaction. Fayed lost. his son to their murderous activities; in my. occasional communications with former MI5/MI6 employees I have been informed that a. "permanent solution" is not uncommon for opponents of the. British secret police. I have lost health and financially, but am obviously well enough to keep fighting my. case. Others have lost much more than I. If the joke which is British. "law enforcement" refuses. to enforce laws against the security services then that. is something that is recognised in other countries and Britains stock correspondingly falls. Not. that it has very far to fall; the days when England had. any say in the world are long gone.

MI5 Want These Faxes. to Continue

Before the holiday, I said that. if MI5s harassment of me stopped, then I would cease. my complaints. They have known very well that if they continued to harass me then I would resume the fax campaign in. the autumn. Yet they. have not stopped persecuting me. Recently a woman outside my domicile screamed her head off. with abuse in the direction of my window; and on. Saturday 2 October, when I was shopping at a nearby supermarket, a man shouted the particularly vile sexual swear. word which I have heard many times before over the last few. years.

MI5s attitude. shows complete arrogance. Yet it also shows that they want the faxes to. continue and deliberately try to provoke me into sending further faxes. The reasons. for this are given in the first paragraphs of this article; the MI5 operatives. who persecute me have nothing else to do with their time; to make their campaign, against. an apparently unreacting target, have some value, they have to force me to. react in some way against their actions; and by reacting in this way,. by bringing their campaign to the attention of. British politicians, I play into their hands, by giving their campaign the attention and importance which they. feel it deserves.

In the short term, by sending these. faxes, perhaps I am doing something they want me to do, but in the. longer term it is undoubtedly more in my interest than theirs for their. activities to be exposed. If their operatives. truly do wish to see these faxes continued then they are

committing a serious mistake, because. it significantly increases the risk if M.P.s (some of whom already know about MI5s activities against me). are advised of my. side of the story.

I will continue to monitor and record the secret services. activities against me over the next few weeks. If they diminish and cease, as. I hope they will, then I may be able to call a halt to these faxes; but that. it something which is entirely up to them; recently. their continued harassment makes clear that they do wish the. faxes to continue, and in all sincerity I do think. they will continue their activities and make it impossible for me to cease these faxes. It may trouble you to. receive these articles, but it troubles me much more to. be on the receiving end of a national persecution campaign; and while Britain does not have. free speech provisions as does Canada in the. Charter of Rights and Freedoms, and the US in the first amendment to the constitution,. in practice I do not think anyone. is going to try to have me locked up for speaking the truth. I. still cherish the hope that the veracity I express will be shown for what it is, and that the truth will prevail and make. me free.

Removing the Mask of. Anonymity from the MI5 Operatives

Undoubtedly. one factor encouraging the MI5 agents actions against me has been the fact that they can shelter behind. a mask of anonymity while they carry out their abuse. This. is both a sign of their realisation that their actions are criminal; for crimes are harder to. pin down and make a coherent complaint about when their perpetrators are unknown;. and it is a sign of their cowardice, since they lack the backbone to say. things to my face themselves; instead they almost. always rely on third parties to carry out the actual acts of. abuse.

On a few occasions I have seen the perpetrators, but on each. occasion they have managed to preserve their anonymity. They travelled. on the same British Airways flight as me in 1994; but BA have ever since. refused to give up the passenger. list for the flight, and the police and lawyers have proved useless in obtaining their identities from the list.. Also one of them followed. me into A&E department of Ottawas Civic Hospital a couple of years ago, and. gave his name as (if I heard correctly) "Alan Holdsworth"; but the doctor refused to give out. his identity when I later tried. to speak to him.

If only we knew the identities. of the individual operatives, then it would be possible to find out. the identity of their employing organisation. But I think. we know the latter already, since I have been accusing them on internet newsgroups for four and a half years now,. and they have never denied my guess. Indeed, when I. was travelling in January 1996 back to Ottawa, two. youths on the (British Airways again, unfortunately) flight made a lot of noise at me, one of them saying to. the other that I "didnt know who we are". That is a wafer-thin denial;. I had been saying for a year that they were MI5, so a stronger denial would be necessary if. my guess were truly mistaken. I think the. lukewarm denial was worse than no denial at all, since. it confirmed my guess that the employing agency was indeed. MI5.

Conclusion

It has been suggested. to me that by sending these faxes I could be making trouble for myself; but. I dont think so. My psychiatrist knows what I am doing; indeed I have given him. a couple of these articles for him to cast an. eye over.

I dont want to have to send faxes for the next year,. or the year after that. But that is entirely up to MI5. If they continue to persecute. me then I am forced into defending myself. The ball is in their court, and. it is entirely up to. them what they do. If as I suspect it is their intention that these faxes continue,. if that is what they insist will happen then so be. it.

Oh that is what you meant. So an amplifier has 4 sides?

Anyway, examples of what you are looking for exist
in most amplifiers. They are often called blocking
capacitors. They charge to the DC voltage but pass
the signal. They are not particularly good voltage
sources, but that is their role in the circuit, and
they do it admirably well.

MI5 Persecution Update: Friday 31. March, 2000

22,544. Faxes Delivered in Three Years, and Still No Breakthrough

In the last three years I have sent at least 22,544 faxes to. recipients in the UK, of which at least 13,974 have. gone to Westminster. Last weekend alone I sent 832 completed faxes. to politicians, the media and various others, on. the subject of MI5s mistreatment of me these last ten years.

I believe some of the recipients know of MI5s. actions against me in the last decade; yet. they maintain strict "omerta" in fear of the security services persecution. actions being made public.

MI5 Insist that these Faxes must. Continue

Between September 1999 and mid-January 2000, the persecutors, whoever. they might be, mostly left. me alone. I counted only three incidents in almost five months - which is a lower rate than at any time since June 1990,. when this business. started.

By leaving me. alone for several months, the "oppressors" were making an implicit assurance that they. would continue to leave me alone in the future. On 11 January I posted to an internet. newsgroup accepting what I saw as their assurance. of no further harassment, stating that I would cease sending these. faxes - which is the only thing I do in my defence - if they continued to leave me alone. And for two. weeks I did indeed refrain. from distributing these articles.

But MI5 acted in bad faith. From the last week. of January until the beginning of March, they resumed. their hate campaign against me with a vengeance. They even put people in my road. three times in February, one instance of which. I recorded. They resumed their normal behaviour of bugging my phone and house, listening to where I would. go, and then placing people in that location to. "aggravate and annoy" me.

What MI5 did in. February is plainly a contravention of the Protection from Harassment Act 1997, since. it has caused me "alarm and distress" as specified in the Act. But it. is a waste of time going to the police with a complaint, since the police have done, and will. do, absolutely nothing. I complained to the Metropolitan Police in 1995, and they refused to take. my complaint. When I complained again in 1999,. the detective sergeant laughed at my complaint, with the words, "It's an absolute load. of rubbish. I don't investigate rubbish.. I can't be more blunt or to the point than that." It is useful to remember that. the Met also treated Stephen Lawrences parents with similar discourtesy;. police prejudices are similar

in. my case, so I can take some comfort from that case and hope that one day I will get a. fair hearing.

MI5 acted in bad. faith, but they also acted with arrogance. They do not care if I send 800 faxes every. weekend, since they know I cannot prove my claims, and the recent Shayler case shows. how weak external oversight is of the secret services. But they. acted with more than arrogance - the MI5 agents actually want my faxes to. continue, they insist that these faxes continue, since my communications give them an. excuse to continue their activities, and continue. in the paid employ of the secret service. Despite their use of. diverse proxies over the last ten years, it is the same MI5 officers behind the campaign all the time - I have seen one of them. on three occasions in Canada over a period of years, and it is a. safe belief that that same person continues to be paid. for his "work" in harassing me in London now. The average cost. of an MI5 employee is some 75,000 per annum, so one may infer that their officers. are amply compensated; their insistence that "hostilities" are maintained. is understandable when placed in this. light.

Of course. That is writing with precision, as I said.

> > Well, there is no energy flowing through the '+' points.
>
> I proved that energy is flowing through the '+' points
> before the line is cut.

Unfortunately, this has not being proved as yet, but
merely assumed.

> Superposition proves that there
> is energy flowing through those points.

I thought that you had previously agreed that it was
not appropriate to superpose power. This can be
revisited if you have changed your mind.

> > And I have no issue if you wish to claim that there
> > are reflections at these points, though I might use
> > 'bouncing' to differentiate from reflections occuring

No. I was merely offering an alternate term tht you might
use when claiming that they reflect, since reflect causes
you such grief.

> > No energy is flowing (q.v. IEEE definition of

> the QEX editors.

That argument was more about whether the output impedance
of an amateur transmitter was well defined. In my encounters
with the arguments I don't recall any claim that if it
was well defined and equal to the line impedance, then
there would be a reflection. If this claim was made,
then someone needed to revisit the books.

> > Web references and Spice models which agree that "the

>
> No, I asked you to measure the reflection coefficients
> and report the results. You refused to do so.

Exactly. You refused to check your textbooks. You refused to
review the web references. You refused to examine the
spice models. Instead you ask me to measure something and
expect me to believe that some measurement I make will
convince you. Just another way to delay.

> If the issue
> had ever been resolved, it would be common knowledge and
> we wouldn't be arguing about it.

There is only one place that this is being argued. If you
would review your textbooks, if you would look at the web
references, or if you would examine the spice models, you
would learn that the argument was settled long ago.
(Actually, there probably never was an argument, except
on r.r.a.a.)

MI5 Persecution Update: Friday 7. April, 2000

22,544 +. 837 = 23,381

Last weekend I. delivered another 837 faxes to politicians and the media on the subject of the security service. conspiracy which has destroyed my life. This brings the total in the last three. years to at least 23,381. These. totals do not include partially delivered faxes.

Some of the recipients of these faxes must know. that what I say is true; and I hope to motivate those people. to acknowledge the reality of the harassment which has. followed me for ten years. It takes much time to transmit these articles, but as OCG MD Simpson-Wells said to. me in 1992, you have. to be a good communicator if you are to succeeed.

Harassment. in February 2000

Following a quiet period of almost five. months, the persecution resumed with a vengeance. in late January/February 2000. At this time I was at home in Clapham, London and was a relatively easy target. for the persecutors. They have my. house bugged, for audio and I believe video in some rooms as well; so. they can find out easily where I will be going on a particular day, and place people in that location to mouth. words of abuse at me. (I know the last sentence. sounds like classic paranoia, but it happens to be true,. and some of the people reading this know it to be true.)

On Friday 11 February 2000 I went shopping in. Croydon, to buy a watch at H. Samuels jewellers in the Whitgift Centre. While I was. there two youths came into the shop, one of them quietly. uttered an obscenity at me, and they immediately. walked out. They showed no interest in the shop.

That Sunday I met with a friend in Clapham, who started. needling me about "do you know. anything about the CIA and FBI?". Rather unsubtle, and worrying considering Ive. known this guy for 20 years. From the words and demeanour of this "friend". and others in February, I saw that the persecutors. have again been trying to separate from me what remains of my social. life.

Incidents in my. Road in February

MI5 very rarely place people in my home road to harass me,. but such was their persecutory fervour in. February that they did so on three separate occasions. On the first such occasion, I was met my. two youths who, grinning, said a deeply offensive sexual obscenity. at me - at which I

coughed at them, so. they called me a "wanker". This incident is safely recorded on minidisc-walkman, but because. of the offensive nature of their abuse the recording. will not be made public.

Another incident very early in. the morning of Sunday 20/Feb/2000 occurred outside my home, following an evening. in Croydon with some schoolfriends. Again there were two youths - for some. reason the persecutors always travel in twos or. threes, very rarely is there just one of them. - perhaps they need a group to bolster their courage, perhaps just one of them wouldnt have the guts to say. something unpleasant. One of the youths said quietly, and bitterly, "shitty,. very shitty".

Anyway, in. March there were no further incidents near my house in in my road, and our neighbours. are very well disposed towards us, so let us hope that the current quiet. continues.

Source record: 30366

Actually you do and you are getting tiresome.

You made the statement in the subject line no less, that asserted that DV would solve BPL issues.. All you have spouted so far is that DV works and it is available. That is not at issue here. Most of us know of its existence and roughly how it works. Most of us also know that in low S/N conditions it DOESN'T work.

You referenced websites that contain no information about the noisefloor handling limitations or how (measured) it works. Even the AOR website doesnt even list the Eb/No spec which would automatically make me not even consider buying it! Listening to recovered audio (quality) is NOT a measure of your claim in the subject line UNLESS it contains someone talking about the Eb/No measurements they had taken. This is why I asked you to provide data from your own experiences. This would have provided useful information to those reading this NG and would have been great interest to many.

If you arent intersted in providing your own or some relevent external data on your published subject there is no point continuing this thread. You can of course issue a retraction and apology for going off your own topic..

While I think sending data over Romex is not a very bright idea, as long as BPL does not radiate in a radio band where it would propagate, I could care less.

I have kept from feeding the troll for a while now, but he keeps coming back.

Make him go away please.

Thank you.

Thanks for alerting me to this device, which is real.

Thanks also for pointing out (in another posting) that the Norton source is a constant current source.

But no, this will not do. The problem is that "We want to investigate a 1/2 wave length of transmission line, excited at one end. How soon is stability reached?"

No doubt, past postings have not so clearly stated the scope of investigation.

Unstated, and perhaps confusing, is the the power level must be limited to some real value.

Also unstated, but reasonably assumed, is the understanding that the exciting source would not be part of the circuit except as needed to provide the excitation.

This last assumption was never achieved because the responders all insisted that the source must be part of the investigation. It was further insisted that the source invert the reflected waves with a -1 reflection factor. Had a +1 factor been acceptable, which is equivalent to the reflection factor of an open circuit, the assumption would have been realized.

Several responders discussed the Norton or Thï¿½venin equivalent circuits. These circuits assume steady state conditions, and are intended to be replacements for groups of components. A very useful concept, but not appropriate for startup excitation of a transmission line unless the intent was to investigate the source AND transmission line as a system.

More later. I as still thinking about the "perfect power source".

No, I'm saying what all the references say - that power
dissipation inside an equivalent source is irrelevant.
Yet you seem convinced that you know the internal power
reflection coefficient. You are contradicting the
references.

Cecil,

It is interesting that you ridicule zero impedance ideal sources, and then you provide an example with a circulator. Do you really think a circulator is more ideal than a good voltage source?

Hi Roger,

Quite a bizarre stance. Do you regularly come to these points of view
without further thought, elaboration, or analysis? It seems you have
assigned some remarkable characteristics to the Norton and Thevenin
source and you don't offer us anything substantive beyond what would
be called "Arthur's proposition."

To cut to the chase, Norton and Thevenin sources are appropriate to
network analysis irrespective of your perception. You should look
closer at your issues of difficulty because it does not reside in
their classic application to classic situations.

>More later. I as still thinking about the "perfect power source".

That's fine, but it is now turning into a mantra rather than a
productive examination. You would do well to spill your guts as to
why you commit so much of the calendar to this thought. Alone, it is
as meaningful as announcing that one is thinking about "cold fusion."

You mean like Ramo & Whinnery in "Fields and Waves ..."
2nd edition, page 291? (begin quote)

In such problems we are often most interested in the ratio
of power in the reflected wave to that in the incident wave,
and this ratio is given by the square of the magnitude of
[rho], as can be shown by considering the Poynting vectors:

Pz-/Pz+ = |rho|^2

end quote.

Pz+ is the forward power Poynting vector. Pz- is the reflected
power Poynting vector. The *NET* Poynting vector is the
difference between those two Poynting vectors.

If Pz+ = Pz-, then the net Poynting vector is zero but
the component Poynting vectors still exist. If you disagree,
please take it up with Ramo & Whinnery.

>battery same exact problem

Hi Myles,

Good. I would still implore you to consider that ground can arrive on the rig through numerous side paths. You say it was on battery power, but is that battery served with a floating charger? Possible path to ground there. Do you use an external keyer with an external power supply (wall wart)? Possible path to ground there. Is your rig connected to your computer for any reason? Possible path to ground there. And so on....

>disconnecting the ant at roof kills the noise so i presume most if
>it is picked up via antenna not sure if this was scientific seems
>true thou

No problem with "scientific method" here, none at all. Unlike the armchair theorists busily pounding conventional thinking into the dust of other threads, you pursuits are vastly more informing.

Now, when you say you disconnect that antenna, that means only the two wires of the dipole and no other connection? If so, replace those two wires with a dummy load to judge how well the path for transmission remains (do a SWR test).

Replace the wires of the dipole with a small (18 inch diameter) recieve loop. How does that perform, noise-wise?

Try using a small portable radio in the vicinity of the elevator shed and do a noise survey, making a map to see if you can find a hot spot.

>Getting inside that room thou or once inside the cabnets might prove
>difficult the building considers the new work up there as sacrade
>grounds now they didn't even paint the room, and can't figure this
>one out, took out the 120v outlet that used to be on the wall for

>cabinets are connected via metal conduit so i presume there is some
>ground made couldn't tell of the motors the wires are in a conduit
>that seems to go tothe motor so i can't see any actual connections

Take a look inside each time you visit. Perhaps in time it will
become more familiar and the solution will leap out at you.

>i was always guessing it wasn't the motor since the noise will occur
>even if the motor isn't turning however i understand now that it could
>be either an antenna or energized during it's still moments

Good observations. Think about this in the context of my suggestion
above about the portable radio.

>the motors are closest to my antena and the cabinets are furthest and

>
>
>i just can't figure why the noise isn't constant thou or exactly
>intermittant ie it can be on 3 off 2 on 4 off 7

This may take more time with you on the roof during high traffic
periods. In the shack, you might want to make a detail log of time of
occurence to see if it correlates to some particular activity.
Obviously this implies the typical morning, lunch, and evening traffic
of the building, but analysis might show a constant noise field.

And, _that_ would be a Great Loss .... how?

Using a Real Newsreader, you could block by Subject: (as well as by
poster.) I find that even before I read a new troll posting, it is
easily identifiable by both Subject: content and poster id. I mark it
for killing (by Subject:) for nn days and never have to encounter
anything in that thread again. Some logic if the poster is killfiled
here and I don't see the Subject: until the first followup to the troll.

Sigh. Over the years this Once Great ng covering antennas has been
slowly overtaken by a handful of twits.

Yes, this is the idea, exactly.

The loaded version is much more complicated than the unloaded version.

Stability is always reached provided power input contains a maximum.

Another example from HP's AN 95-1

b1 = s11*a1 + s12*a2 b2 = s21*a1 + s22*a2

```
Z01 Z02
-------------+-------------
Pfor1-->|-->Pfor2
Pref1<--|<--Pref2
```

|a1|^2 = Pfor1 |b2|^2 = Pfor2
|b1|^2 = Pref1 |a2|^2 = Pref2

> DV would solve BPL issues..

BPL is only data packets containing different CRC sums, since DV are data packets containing similar CRCs', and further, since these data packets contain an identifying number, so the system they are meant for will recognize them, how do you think they will cause any trouble.

If it is the "interfering harmonics", or even the center freqs of the data packets you are referring to, how would you think this interference would be any different than a bunch of p*ss*ed off hams attempting to "jam" DV hams ...

Do you ever do any original thought for yourself?

But then again, those pages contain calls and addresses of hams which are "frequent fliers" on DV, why not go to the "horses mouth--directly?" That is how I first got acquainted with implementing DV ... these guys express the true spirit of amateur--they support experimentation and it is my experience, offer advise/help freely ...

Some software works better than others, make sure you try a few. I should point out some has open source, you and others can freely modify the source code/error corrections routings at will. If you are really savvy, you can download the firmware code from patented modems and implement in the freeware--if you OWN such a device--I don't see where you world be making any infringements on the institutions' rights/patents.

You will find people at all levels here ... beginners to those which have been here for, literally, decades ...

Regards,
JS

Cecil,

As usual, you have taken something generally accepted as true, and then you have added your own special spin. You might have noticed that Ramo & Whinnery did not go into all of the "net" baloney, and neither did HP in AN-95. That stuff is only in your imagination.

The last I heard, energy is a scalar quantity. In the cases we are considering, energy is only positive or zero, not negative. How do two non-negative scalar quantities "flow" past each other, adding up to a "net" of zero, unless the initial quantities themselves are zero?

I agree that the concepts included in R&W and in AN-95 are widely used. However, they were never intended to be distorted into your dream world.

The bouncing traveling wave model is an extremely useful mathematical device. It does not trump physical reality.

Bill,

The AH4 tuner is spec'd to tune 3.5 MHz to 54 MHz with as little as 23 feet of wire. With the AH4 tuner, you should be able to work it. What I would do is mount the tuner at the base of the mast. Get enough twin lead to reach the top of the mast and then enough wire to reach from the top of the mast to whatever tie off points you have for the lower part of the inverted vee. You can build your own twin lead with wire and spacers or buy some. Connect one side of the twin lead to the signal post and the other to the ground post of the tuner. Solder the wires to the opposite end of the twin lead and attach that to a strain relief that you could hoist up the mast. Tie off the loose wire ends and see what happens. If you end up with un-equal lengths of wire to tie off, connect the longer side to the ground end of the tuner.

There are a few lengths that that the tuner can't tune (look at the manual as I don't have mine handy). Remember, the vertical (twinlead) portion of the antenna is part of the wire length so make sure to take that into account.

Translation: I don't have the balls to argue with
Ramo & Whinnery and HP over issues that are more than
obvious to any casual initiated observer.

> The last I heard, energy is a scalar quantity. In the cases we are
> considering, energy is only positive or zero, not negative.

As you well know, the convention is to apply a negative
sign to positive energy flowing in the opposite direction
from the "forward" energy which is arbitrarily assigned
a plus sign. When Ramo & Whinnery say, using Poynting
vectors, that Pz(net) = Pz+ - Pz-, they are not implying
negative power. They are just using the Poynting vector
convention of direction of energy flow in a transmission
line. We are saying the same thing when we say:

P(load) = P(forward) - P(reflected) = P(net)

Transmission lines have the advantage of having only two
directions so '+' can be assigned to one direction and
'-' assigned to the other. It is completely arbitrary -
the signs can be swapped and the results remain the same.

> I agree that the concepts included in R&W and in AN-95 are widely used.
> However, they were never intended to be distorted into your dream world.

See "Translation" above.

Still using that vivid imagination, I see.

Let's see even one reference that mentions explicitly the concept of applying a negative sign to positive energy. Not power, not voltage, not current, not waves, but energy.

If you keep feigning ignorance like that Gene, you are
going to lose all respect. If the Poynting vector has
a negative sign, as used by Ramo & Whinnery, that sign
is an indication of the *direction of energy flow*,
see quote below.

From Ramo & Whinnery:

The Poynting vector is "the vector giving *direction* and
magnitude of *energy flow*". When Ramo & Whinnery hang a
sign on a Poynting vector in a transmission line, it is
an indication of the direction of energy flow.

For pure standing waves,
"The average [NET] value of Poynting vector is zero
at every cross-sectional plane; this emphasizes the
fact that on the average as much energy is carried
away by the reflected wave as is brought by the
incident wave."

What? Reflected waves "carrying" energy? Shame on
Ramo & Whinnery for contradicting the rraa gurus.

It is impossible to satisfy you, Gene. When I quote
reference after reference about reflected power, you
say power doesn't reflect. When I change it to reflected
energy, you ask for a reference.

Really, the wail and torment of your two's grief is no more
sophisticated than: the dog ate my homework. This is a noble quest in
search of a "free lunch."

In the end, it serves absolutely no purpose in trying to resolve the
"confusion" of why a traveling wave antenna has standing wave energy
where the purpose of this thread was strangled in the crib by Cecil
when I dropped that one. ;-)

If "stability" means steady state, a transmission line with any resistance at either end or both ends is less complicated to analyze than the particularly difficult lossless case I used for my analysis which never reaches a true steady state. The presence of resistance allows the system to settle to steady state, and that process can easily and quantifiably be shown. And in two special cases, the process from turn-on to steady state is trivially simple -- If the line is terminated with Z0 (technically, its conjugate, but the two are the same for a lossless line since Z0 is purely resistive), steady state is reached just as soon as the initial forward wave arrives at the far end of the line. No reflections at all are present or needed for the analysis. The second simple case is when the source impedance equals Z0, resulting in a source reflection coefficient of zero. In that case, there is a single reflection from the far end (assuming it's not also terminated with Z0), but no re-reflection from the source, and steady state is reached as soon as the first reflected wave arrives at the source.

Roy Lewallen, W7EL

Assuming that reflection cannot exist without energy,
where does the ExH*t energy in the reflected wave go?

(OK now, everyone hold their breath for an answer.)

Unfortunately for your argument, neither a mouse nor
a battery exists inside a transmission line. Outside
of usually minor heat losses, nothing exists besides
EM waves traveling at the speed of light.

For what it's worth, I use NewsRover to read news. GigaNews is only the source. I' not sure what is a "normal newsreader". *nix people have their favorites and google news people have no contro. I know how to use Outlook but NewsRover gives me much more control. I can filter on header content or message content in a variety of Boolean ways. I can also block senders if the sender doesn't fake his post address.

If you don't know the capabilities of News Rover you can check it out on SandH.com. It is as perfect at retrieving threads as a newsreader can be. And yes, I can kill threads by subject if the authors don't keep messing around with the Subject. In this case, the newsgroup was so dominated by a single poster that blocking made more sense to me. So yes, I am structuring my viewing so as to only see the threads of interest.

Now back to discussions about antennas. 73 and Happy New Year.

Ken

John

Digital systems dont work like that. You can't normally have two system existing in the same bandwidth/frequency and expect that they wont interfere with each other. The DV RX system doesnt want to expend effort decoding the BPL packets at all. Yes it is OFDM but the carrier spacing will be very different from DV. It will just be noise... The only situations where this will work well is if there are periods of no TXing of one station that can be exploited by the other. For all intents and purposes a BPL system transmits 100% of the time even if just sending hardware/sync frames with no data. In other words it just looks like "noise" to the competing system as per my previous posts. The BPL signal WILL "cause trouble".

Depending on the interferring signal makeup it *may* be possible to "fit" one digital signal into the frequency domain gaps of the other, but that would be very difficult to code well. You have to know a lot about the interfering signal and even assume that the BPL developers left effective gaps to exploit. I dont think it is do-able but I'll listen to anyone that can solve it! Hey if I came up with the code I'd make it available under GPL!

You treat the interferring signal as the (new) noise floor and ensure that you are at least the Eb/No margin above that.

A digital signal is very different from a plain SSB voice signal. A digital signal is pretty well a constant amplitude across the RF bandwidth. There are certainly individual carriers but spectrum wise it will just look kind of like it fills the SSB filter response. An SSB voice signal comes and goes depending on speech. The SSB information is in the amplitude domain and in the AOR case DV is in the frequency domain (QPSK). You cant compare interfering signals of both these types unless you think in terms of the filter wide band noise power of each over some fixed time period. SSB voice will tend to have a lower power average than a DV signal of the same peak amplitude. I dont know the figure off hand but I would guess that an obnoxious overcompressed SSB station might be 6-12dB down on the equivalent peak amplitude DV signal. I am sure someone will correct me here.

Also keep in mind that a transitted DV signal probably also employ some time diversity in its forward error correction. The net result of this is that the same part of a section of speech is sent over a number of time periods. (MT63 and some other keyboard modes does this as well) This makes recovery of the data much easier if there is asynchronous pulse noise on the same frequency. Someone jamming a DV signal with an SSB TX for example will do better just to TX wide band noise rather than

just plain talking or whistling. They tend to be seen as pulse like events. The time diversity as mentioned above will make any async interference a non event or at least have minimal impact.

There is also the redundacy of (in the AOR case) the multiple OFDM carriers. I dont remember the number of hand but in the older DigTRX/HDSSTV/Wyman encoding you could afford to lose 3 of the 8 carriers and still get the data through. This would seem then to get past any single tone whistling or CW interference. Of course this time and frequency diversity/redundancy impacts on the data throughout. There will always be some trade-off to make a DV system work universally.

Realizing the above supports you comment that DV gets very little interference from voice SSB stations, but competing with another digital signal of the same bandwidth though is an entirely different story. Think noise bandwidth power.

You might be interested to know that some DVB consortium (US) wanted to tax all A/D and D/A converters sales to support the video/TV industry in light of the newer DSP/PC based "radios" now coming about. It is now possible to create 3 and 4 chip systems that can do most of the donkey work in preprocessing RF signals then feeding it into your regular PC for decoding and decrypting the copy protection they use. If you are interested in such hardware have a look at the gnuradio project. One of the boxes mentioned has the capability of RX and TX of EVERY amateur mode available on HF. It will also do WiFi and a whole lot of other stuff with a suitable RF converter.

I wont bother answering the rest of your post.

"In such problems we are often most interested in the ratio of power in the reflected wave to that in the incident wave, and the ratio is given by the square of the magnitude of [rho] as can be shown by considering the Poynting vectors:"

Terman agrees. On page 98 of his 1955 opus, Terman shows the value of [rho] vs. SWR.

On page 97 Terman writes:
"This definition of standing-wave ratio is sometimes called the voltage standing-wave ratio (VSWR) to distinguish it from the standing-wave ratio expressed as a power ratio which is (Emax/Emin)squared."

Best regards, Richard Harrison, KB5WZI

Ken
You have a direct line with Yahoo who aids and abets kb9...
If they don't care who they support then drop them.
Yahoo is probably happy with what their customers are doing
on the net. Ofcourse if MI5 can't get the other guy write
a letter to the CIA they would know what to do.
